#### Abstract

We are concerned with existence and multiplicity of nontrivial solutions for the Dirichlet problem $\Delta u+|u|^{p-2} u=0$ in $\Omega$, $u=0$ on $\partial \Omega$, where $\Omega$ is a bounded domain of $\mathbb{R}^{n}, n \geqslant 3$, and $p>\frac{2 n}{n-2}$. We show that suitable perturbations of the domain, which modify its topological properties, give rise to a number of solutions which tends to infinity as the size of the perturbation tends to zero (some examples show that the perturbed domains may be even contractible). More precisely, we prove that for all $k \in \mathbb{N}$, if the size of the perturbation is small enough (depending on $k$ ), there exist at least $k$ pairs of nontrivial solutions, which concentrate near the perturbation as the size of the perturbation tends to zero. The method we use, which is completely variational, gives also further informations on the qualitative properties of the solutions; in particular, these solutions (which may change sign) do not have more than $k$ nodal regions and at least two solutions (which minimize the corresponding energy functional) have constant sign.

## Résumé

Nous étudions l'existence et la multiplicité de solutions pour le problème de Dirichlet $\Delta u+|u|^{p-2} u=0, u \neq 0$ en $\Omega, u=0$ sur $\partial \Omega$, où $\Omega$ est un ouvert borné de $\mathbb{R}^{n}, n \geqslant 3$, et $p>\frac{2 n}{n-2}$. Nous démontrons que l'existence et le nombre de solutions sont liés à certaines perturbations du domaine, qui modifient ses propriétés topologiques. Chaque perturbation dépend d'un paramètre $\varepsilon$ (l'épaisseur de la perturbation); quand $\varepsilon \rightarrow 0$, le nombre de solutions tend à l'infini et les solutions se concentrent près de la perturbation (des examples montrent que les domaines perturbés peuvent même être contractiles). Plus précisément, nous prouvons que pour tout $k \in \mathbb{N}$ il existe $\varepsilon_{k}>0$ tel que, pour tout $\left.\varepsilon \in\right] 0, \varepsilon_{k}[$, le problème a au moins $k$ paires de solutions. La méthode que nous suivons, qui est complètement variationnelle, donne aussi des informations sur les propriétés qualitatives des solutions. En particulier, ces solutions (qui peuvent changer de signe) ne peuvent pas avoir plus que $k$ régions nodales; de plus, au moins deux solutions (qui minimisent la fonctionnelle de l'énergie) ont signe constant.

## 1. Introduction

Let us consider the problem

$$
P(\Omega) \quad\left\{\begin{array}{lll}
\Delta u+|u|^{p-2} u=0, & u \not \equiv 0 & \text { in } \Omega \\
u=0 & \text { on } \partial \Omega
\end{array}\right.
$$

where $\Omega$ is a bounded domain of $\mathbb{R}^{n}, n \geqslant 3$, and $p>\frac{2 n}{n-2}$ is a fixed exponent $\left(\frac{2 n}{n-2}\right.$ is the critical Sobolev exponent).
In this paper we show that suitable perturbations of a given domain give rise to solutions of the problem in the perturbed domains; when the size of the perturbation tends to zero, the number of the solutions tends to infinity while the solutions concentrate as Dirac masses near the perturbation; this perturbation is realized by removing a thin subset of the domain in such a way to modify its topological properties (see Theorem 2.1 and Remark 2.2).

It is well known that, when $2<p<\frac{2 n}{n-2}, P(\Omega)$ has solutions in any domain $\Omega$. On the contrary, when $p \geqslant \frac{2 n}{n-2}$, the problem has no solution if $\Omega$ is starshaped (see [21]) while it has infinitely many solutions if $\Omega$ is, for example, an annulus (see [8]).

For $p=\frac{2 n}{n-2}$, a sufficient condition for the existence of a positive solution is that $\Omega$ has nontrivial topology, in a suitable sense (see [1]); this condition is only sufficient but not necessary, as shown by some examples of contractible domains where the problem has positive solutions for $p=\frac{2 n}{n-2}$ (see [5,7,16,18]). For $p>\frac{2 n}{n-2}$, this nontriviality condition of the domain is neither a sufficient nor a necessary condition; in fact, nonexistence results hold for some $p>\frac{2 n}{n-2}$ in some nontrivial domains (see [17,19]) while an arbitrarily large number of solutions can be obtained in some contractible domains for all $p>\frac{2 n}{n-2}$ (see [20]).

It is also worth pointing out that existence of solutions in the supercritical case has been proved even in some "nearly starshaped" domains (see the definition introduced in [11]) for $p$ sufficiently close to $\frac{2 n}{n-2}$ (see $[10,12,13]$ ) or for $p$ large enough (see [14]); on the other hand, a different definition of "nearly starshaped" domain is used in [6] in order to extend Pohožaev's nonexistence result to nonstarshaped domains when $p$ is large enough.

Let us observe that in [20] several perturbations have been used in order to obtain several solutions in contractible domains. On the contrary, the result proved in the present paper shows that a unique perturbation can produce an arbitrarily large number of solutions.

In order to overcome the difficulties related to the presence of the supercritical exponent, we proceed as follows: we modify the nonlinear term $|u|^{p-2} u$ in such a way that the modified nonlinearity $g(x, u)$ has subcritical growth outside a neighbourhood of the perturbation; then (exploiting also the symmetry of the domain with respect to an axis) we use topological methods of Calculus of Variations to find multiple solutions of the modified problem in the perturbed domain; we also show that, as the size of the perturbation tends to zero, these solutions concentrate as Dirac masses near the perturbation (where the nonlinear term has not been modified); finally, we prove that these solutions solve also the unmodified problem when the size of the perturbation is small enough.

## 2. Notations and statement of the main result

Let $\Omega$ be a bounded domain of $\mathbb{R}^{n}$, having radial symmetry with respect to the $x_{n}$-axis, that is

$$
\begin{equation*}
x=\left(x_{1}, \ldots, x_{n}\right) \in \Omega \quad \Longleftrightarrow \quad\left(\left(\sum_{i=1}^{n-1} x_{i}^{2}\right)^{1 / 2}, 0, \ldots, 0, x_{n}\right) \in \Omega \tag{2.1}
\end{equation*}
$$

Let $x^{1}=\left(0, \ldots, 0, x_{n}^{1}\right), x^{2}=\left(0, \ldots, 0, x_{n}^{2}\right), x^{3}=\left(0, \ldots, 0, x_{n}^{3}\right)$ be three points of the $x_{n}$-axis which satisfy

$$
\begin{equation*}
x_{n}^{1}<x_{n}^{2}<x_{n}^{3}, \quad x^{1} \notin \bar{\Omega}, x^{2} \in \Omega, x^{3} \notin \bar{\Omega} . \tag{2.2}
\end{equation*}
$$

For all $\varepsilon>0$, set

$$
\begin{equation*}
\chi_{\varepsilon}=\left\{x \in \mathbb{R}^{n}: \sum_{i=1}^{n-1} x_{i}^{2}<\varepsilon^{2}, x_{n}^{1}<x_{n}<x_{n}^{3}\right\} \tag{2.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\Omega_{\varepsilon}=\Omega \backslash \bar{\chi}_{\varepsilon} . \tag{2.4}
\end{equation*}
$$

Since the domain $\Omega_{\varepsilon}$ has radial symmetry with respect to the $x_{n}$-axis for all $\varepsilon>0$, it is natural to look for solutions of problem $P\left(\Omega_{\varepsilon}\right)$ among the functions which have the same symmetry. Thus, we consider the subsets of $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$, $H_{0}^{1,2}(\Omega)$ which consist of the functions radially symmetric with respect to the $x_{n}$-axis and denote by $H_{S}\left(\Omega_{\varepsilon}\right), H_{S}(\Omega)$ these subspaces. Moreover, we intend that every function of $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$ is extended in all of $\Omega$ by the value zero outside $\Omega_{\varepsilon}$. In these spaces we shall use the norms

$$
\|D u\|_{2}=\left(\int_{\Omega}|D u|^{2} \mathrm{~d} x\right)^{1 / 2}
$$

and

$$
\|u\|_{q}=\left(\int_{\Omega}|u|^{q} \mathrm{~d} x\right)^{1 / q} \quad \forall u \in L^{q}(\Omega), \quad q \geqslant 1 .
$$

Theorem 2.1. Let $p>\frac{2 n}{n-2}$, $\Omega$ be a bounded domain radially symmetric with respect to the $x_{n}$-axis, $x^{1}, x^{2}, x^{3}$ be three points of the $x_{n}$-axis satisfying condition (2.2) and, for all $\varepsilon>0, \chi_{\varepsilon}$ and $\Omega_{\varepsilon}$ be the domains defined in (2.3) and (2.4). Then, for all positive integer $k$, there exists $\bar{\varepsilon}_{k}>0$ such that, for all $\left.\varepsilon \in\right] 0, \bar{\varepsilon}_{k}\left[\right.$, problem $P\left(\Omega_{\varepsilon}\right)$ has at least $k$ pairs of solutions $\pm u_{1, \varepsilon}, \ldots, \pm u_{k, \varepsilon}$ in $H_{S}\left(\Omega_{\varepsilon}\right) \cap L^{p}\left(\Omega_{\varepsilon}\right)$, which, for all $i=1, \ldots, k$, satisfy:
(a) $\lim _{\varepsilon \rightarrow 0} \int_{\Omega_{\varepsilon}}\left|D u_{i, \varepsilon}\right|^{2} \mathrm{~d} x=0$,
(b) $\lim _{\varepsilon \rightarrow 0} \int_{\Omega_{\varepsilon}}\left|u_{i, \varepsilon}\right|^{p} \mathrm{~d} x=0$,
(c) $\lim _{\varepsilon \rightarrow 0} \sup \left\{\left|u_{i, \varepsilon}(x)\right|: x \in \Omega_{\varepsilon} \backslash \chi_{\rho}\right\}=0 \forall \rho>0$,
(d) $\lim _{\varepsilon \rightarrow 0} \sup \left\{\left|u_{i, \varepsilon}(x)\right|: x \in \Omega_{\varepsilon} \cap \chi_{\rho}\right\}=+\infty \quad \forall \rho>0$,
(e) $\lim _{\varepsilon \rightarrow 0} \int_{\Omega_{\varepsilon} \cap \chi_{\rho}}\left|u_{i, \varepsilon}\right|^{q} \mathrm{~d} x=+\infty \quad \forall q>\frac{n}{2}(p-1), \forall \rho>0$.

The proof is reported in Section 3, where also other properties of the solutions are specified (see Propositions 3.8 and 3.9).

Remark 2.2. A result analogous to Theorem 2.1 holds in some more general perturbed domains. In fact, let $\Omega$, $x^{1}, x^{2}, x^{3}$ be as in Theorem 2.1; consider a sequence of subdomains $\Omega_{j}$ of $\Omega$, satisfying the radial symmetry condition (2.1) for all $j \in \mathbb{N}$; now, set

$$
\begin{equation*}
\operatorname{cap}\left(\Omega \backslash \Omega_{j}\right)=\inf \left\{\int_{\mathbb{R}^{n}}|D u|^{2} \mathrm{~d} x: u \in C_{0}^{\infty}\left(\mathbb{R}^{n}\right), u(x) \geqslant 1 \forall x \in \Omega \backslash \Omega_{j}\right\} \tag{2.5}
\end{equation*}
$$

and assume that
(a) $\lim _{j \rightarrow \infty} \operatorname{cap}\left(\Omega \backslash \Omega_{j}\right)=0$,
(b) for all $j \in \mathbb{N}$ there exists $\rho_{j}>0$ such that $\chi_{\rho_{j}} \cap \Omega_{j}=\emptyset$.

Then, arguing as in the proof of Theorem 2.1, one can prove that, for all $p>\frac{2 n}{n-2}$, problem $P\left(\Omega_{j}\right)$, for $j$ large enough, has at least $k$ pairs of solutions $\pm u_{1, j}, \ldots, \pm u_{k, j}$ in $H_{S}\left(\Omega_{j}\right) \cap L^{p}\left(\Omega_{j}\right)$, which, as $j \rightarrow \infty$, present the same asymptotic behaviour that the solutions given by Theorem 2.1 present as $\varepsilon \rightarrow 0$ (see (a)-(e) in Theorem 2.1 as well as the properties described in Propositions 3.8 and 3.9).

Finally, let us remark that the methods we use in this paper can be easily adapted to deal with more general nonlinear terms having supercritical growth.

Examples 2.3. Theorem 2.1 allows us to obtain an arbitrarily large number of solutions even in some contractible domains. Consider, for example, the domain $A \backslash \bar{\chi}_{\varepsilon}$ (a pierced annulus) where $A$ is the annulus

$$
A=\left\{x \in \mathbb{R}^{n}: 0<r_{1}<|x|<r_{2}\right\}
$$

and $\chi_{\varepsilon}$ is the cylinder defined as in (2.3) with $x_{n}^{1}=0$ and $x_{n}^{3}>r_{2}$. It is clear that, because of this choice of $x^{1}$ and $x^{3}, A \backslash \bar{\chi}_{\varepsilon}$ is a contractible domain for all $\varepsilon>0$; moreover, Theorem 2.1 applies when $\varepsilon>0$ is small enough and guarantees the existence of an arbitrarily large number of solutions. As $\varepsilon \rightarrow 0$, the number of solutions tends to infinity and the solutions concentrate near points of the $x_{n}$-axis. Notice that these solutions do not converge as $\varepsilon \rightarrow 0$ to solutions of the problem in the limit domain (i.e. the annulus $A$ where, on the other hand, it is easy to find infinitely many radial solutions).

Let us remark that, in order to have an arbitrarily large number of solutions in contractible domains, in [20] some domains $\Omega_{\varepsilon}^{h}$ of the following form have been considered: $\Omega_{\varepsilon}^{h}=\Omega^{h} \backslash \bigcup_{j=1}^{h} \bar{\chi}_{\varepsilon}^{j}$ where $\chi_{\varepsilon}^{j}$, for $j=1, \ldots, h$, is the cylinder of the form (2.3) with $x_{n}^{1}=j$ and $x_{n}^{3}=j+1$ and $\Omega^{h}=T^{h} \backslash \bigcup_{j=1}^{h} \overline{B\left(c_{j}, r_{j}\right)}$, where

$$
\begin{equation*}
T^{h}=\left\{x=\left(x_{1}, \ldots, x_{n}\right) \in \mathbb{R}^{n}: \sum_{i=1}^{n-1} x_{i}^{2}<1,0<x_{n}<h+1\right\} \tag{2.6}
\end{equation*}
$$

and $B\left(c_{j}, r_{j}\right)$ is the ball of radius $\left.r_{j} \in\right] 0,1 / 2\left[\right.$ and centre $c_{j}=(0, \ldots, 0, j) \in \mathbb{R}^{n}$. In [20] it is proved that for all $j=1, \ldots, h$ there exists a solution of $P\left(\Omega_{\varepsilon}^{h}\right)$ whose positive or negative part concentrates as $\varepsilon \rightarrow 0$ near the cylinder $\chi_{\varepsilon}^{j}$. Now, it is clear that Theorem 2.1 can be applied in the domain $\Omega^{h}$ with $h$ separate terns of points $x^{1}, x^{2}, x^{3}$ satisfying condition (2.2); so, for each $j=1, \ldots, h$, for $\varepsilon$ small enough, we obtain many solutions localized near $\chi_{\varepsilon}^{j}$, whose number tends to infinity as $\varepsilon \rightarrow 0$.

Notice that, taking into account Remark 2.2, similar multiplicity results can be obtained also in contractible domains $\Omega_{r}^{s}$ of the form

$$
\begin{equation*}
\Omega_{r}^{s}=\left\{x=\left(x_{1}, \ldots, x_{n}\right) \in \mathbb{R}^{n}: 1<|x|<r,\left(\sum_{i=1}^{n-1} x_{i}^{2}\right)^{1 / 2}>s x_{n}\right\} \tag{2.7}
\end{equation*}
$$

for all $r>1$, when $s>0$ is small enough.
Domains of this type have been also considered in [10,12-14]. When $p>\frac{2 n}{n-2}$ is a fixed exponent, the concentration phenomena, which allow us to obtain the multiplicity result proved in the present paper, occur as $s \rightarrow 0$; on the contrary, other different concentration phenomena, which arise as $p \rightarrow \frac{2 n}{n-2}$ (see [10,12,13]) or $p \rightarrow+\infty$ (see [14]), have been used to find solutions for all $r>1$ and $s>0$, not necessarily small, when $p$ is close to $\frac{2 n}{n-2}$ or it is large enough.

In the case $p \leqslant \frac{2 n}{n-2}$, the solutions of $P(\Omega)$ are obtained as critical points of the functional

$$
\tilde{f}(u)=\frac{1}{2} \int_{\Omega}|D u|^{2} \mathrm{~d} x-\frac{1}{p} \int_{\Omega}|u|^{p} \mathrm{~d} x .
$$

In the case $p>\frac{2 n}{n-2}$, there are some difficulties in dealing with this functional. Therefore, we introduce the following modified functional $f_{\varepsilon}: H_{S}\left(\Omega_{\varepsilon}\right) \rightarrow \mathbb{R}$, defined by

$$
\begin{equation*}
f_{\varepsilon}(u)=\frac{1}{2} \int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x-\int_{\Omega_{\varepsilon}} G(x, u) \mathrm{d} x, \tag{2.8}
\end{equation*}
$$

where $G(x, u)=\int_{0}^{u} g(x, t) \mathrm{d} t$ with $g(x, t)$ defined as follows. For all $x \in \Omega \cap \bar{\chi}_{1}$ we set $g(x, t)=|t|^{p-2} t$. If $\Omega \backslash \bar{\chi}_{1} \neq \emptyset$, in order to define $g(x, t)$ for $x \in \Omega \backslash \bar{\chi}_{1}$, we first remark that

$$
\begin{equation*}
\inf \left\{\int_{\Omega \backslash \bar{x}_{1}}|D u|^{2} \mathrm{~d} x: u \in H_{0}^{1,2}(\Omega), \int_{\Omega \backslash \bar{x}_{1}} u^{2} \mathrm{~d} x=1\right\}>0 ; \tag{2.9}
\end{equation*}
$$

then we choose $t_{0}>0$ small enough such that

$$
\begin{equation*}
(p-1) t_{0}^{p-2}<\inf \left\{\int_{\Omega \backslash \bar{x}_{1}}|D u|^{2} \mathrm{~d} x: u \in H_{0}^{1,2}(\Omega), \int_{\Omega \backslash \bar{x}_{1}} u^{2} \mathrm{~d} x=1\right\} ; \tag{2.10}
\end{equation*}
$$

hence, for all $x \in \Omega \backslash \bar{\chi}_{1}$, we set

$$
g(x, t)= \begin{cases}|t|^{p-2} t & \text { if }|t| \leqslant t_{0}  \tag{2.11}\\ t_{0}^{p-1}+(p-1) t_{0}^{p-2}\left(t-t_{0}\right) & \text { if } t \geqslant t_{0} \\ -t_{0}^{p-1}+(p-1) t_{0}^{p-2}\left(t+t_{0}\right) & \text { if } t \leqslant-t_{0}\end{cases}
$$

Let us remark that this choice of $t_{0}$ implies the existence of a constant $\tilde{c}>0$ such that

$$
\begin{equation*}
\int_{\Omega \backslash \overline{\mathrm{x}}_{1}}\left[|D u|^{2}-g(x, u) u\right] \mathrm{d} x \geqslant \tilde{c} \int_{\Omega \backslash \bar{\chi}_{1}}|D u|^{2} \mathrm{~d} x \quad \forall u \in H_{0}^{1,2}(\Omega), \tag{2.12}
\end{equation*}
$$

as one can easily verify.
Notice that all nontrivial critical points of $f_{\varepsilon}$ belong to the set

$$
\begin{equation*}
M_{\varepsilon}=\left\{u \in H_{S}\left(\Omega_{\varepsilon}\right): u \not \equiv 0, f_{\varepsilon}^{\prime}(u)[u]=0\right\} . \tag{2.13}
\end{equation*}
$$

The solutions of problem $P\left(\Omega_{\varepsilon}\right)$ will be obtained, for $\varepsilon>0$ small enough, as critical points for $f_{\varepsilon}$ constrained on $M_{\varepsilon}$.

## 3. Proof of Theorem 2.1 and behaviour of the solutions

Lemma 3.1. For all $\varepsilon>0$, the functional $f_{\varepsilon}$ (see (2.8)) is well defined and belongs to the class $C^{2}$. Moreover, the following properties hold.
(a) Let $u \in H_{S}\left(\Omega_{\varepsilon}\right), u \not \equiv 0$; then either $f_{\varepsilon}^{\prime}(t u)[u]>0 \forall t>0$ (what happens, for example, if $u \equiv 0$ in $\chi_{1}$ ) or there exists a unique $\bar{t}>0$ such that $\bar{t} u \in M_{\varepsilon}$; in the second case, $\left.f_{\varepsilon}^{\prime}(t u)[u]>0 \forall t \in\right] 0, \bar{t}\left[\right.$ and $f_{\varepsilon}^{\prime}(t u)[u]<0 \forall t>\bar{t}$ (the second case occurs, for example, if $u \equiv 0$ in $\Omega_{\varepsilon} \backslash \chi_{1}$ ).
(b) For all $\varepsilon>0$ such that $M_{\varepsilon} \neq \emptyset$, we have $\inf _{M_{\varepsilon}} f_{\varepsilon}>0$.
(c) There exists $\bar{\varepsilon}>0$ such that $\left.M_{\varepsilon} \neq \emptyset \forall \varepsilon \in\right] 0, \bar{\varepsilon}[$.
(d) $\lim _{\varepsilon \rightarrow 0} \inf _{M_{\varepsilon}} f_{\varepsilon}=0$.
(e) If $M_{\varepsilon} \neq \emptyset$, then $M_{\varepsilon}$ is a $C^{1}$-manifold of codimension 1 .
(f) Every critical point for $f_{\varepsilon}$ constrained on $M_{\varepsilon}$ is a critical point for $f_{\varepsilon}$.

Proof. First, let us remark that the functionals

$$
\begin{equation*}
u \longrightarrow \int_{\Omega_{\varepsilon} \backslash \bar{\chi}_{1}} G(x, u) \mathrm{d} x \text { and } u \longrightarrow \int_{\Omega_{\varepsilon} \cap \chi_{1}} G(x, u) \mathrm{d} x, \tag{3.1}
\end{equation*}
$$

defined respectively in $L^{2}\left(\Omega_{\varepsilon} \backslash \bar{\chi}_{1}\right)$ and in $L^{p}\left(\Omega_{\varepsilon} \cap \chi_{1}\right)$, are $C^{2}$-functionals. Moreover, notice that

$$
\begin{equation*}
\int_{\Omega_{\varepsilon} \backslash \bar{\chi}_{1}} u^{2} \mathrm{~d} x \leqslant \bar{c} \int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x \quad \forall u \in H_{0}^{1,2}\left(\Omega_{\varepsilon}\right) \tag{3.2}
\end{equation*}
$$

for a suitable constant $\bar{c}>0$ and, for all $\varepsilon>0$, there exists $\bar{c}_{\varepsilon}>0$ such that

$$
\begin{equation*}
\left(\int_{\Omega_{\varepsilon} \cap \chi_{1}}|u|^{p} \mathrm{~d} x\right)^{2 / p} \leqslant \bar{c}_{\varepsilon} \int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x \quad \forall u \in H_{S}\left(\Omega_{\varepsilon}\right) \tag{3.3}
\end{equation*}
$$

Hence, by standard arguments, it is easy to verify that $f_{\varepsilon}$ is a well defined $C^{2}$-functional in $H_{S}\left(\Omega_{\varepsilon}\right)$.
(a) Notice that, for all $t>0$,

$$
f_{\varepsilon}^{\prime}(t u)[u]=t\left[\int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x-\int_{\Omega_{\varepsilon}} \frac{g(x, t u)}{t} u \mathrm{~d} x\right]
$$

where (by the definition of $g$ ) the function $t \mapsto \int_{\Omega_{\varepsilon}} \frac{g(x, t u)}{t} u \mathrm{~d} x$ is strictly increasing in $] 0,+\infty[$ for all $u \not \equiv 0$. Then the assertion (a) follows, taking also into account that $g(x, t u) u=t^{p-1}|u|^{p}$ if $u \equiv 0$ in $\Omega_{\varepsilon} \backslash \chi_{1}$ while $g(x, t u) u \leqslant$ $(p-1) t_{0}^{p-2} t u^{2}$ if $u \equiv 0$ in $\chi_{1}$.
(b) From property (a) we infer that, for all $u \in M_{\varepsilon}$,

$$
\begin{equation*}
f_{\varepsilon}(u) \geqslant f_{\varepsilon}(t u) \quad \forall t \geqslant 0 . \tag{3.4}
\end{equation*}
$$

On the other hand, we have $f_{\varepsilon}^{\prime}(0)=0$ and $f_{\varepsilon}^{\prime \prime}(0)[u, u]=\int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x$. Therefore there exists $r>0$ and $\alpha>0$ such that

$$
\inf \left\{f_{\varepsilon}(u): u \in H_{S}\left(\Omega_{\varepsilon}\right), \int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x=r^{2}\right\} \geqslant \alpha
$$

It follows that

$$
\inf _{M_{\varepsilon}} f_{\varepsilon} \geqslant \alpha>0
$$

(c) Since $x^{2} \in \Omega$, there exists $\rho_{2}>0$ such that $B\left(x^{2}, \rho_{2}\right) \subset \Omega$. Choose $\bar{\varphi} \in H_{S}\left(B\left(x^{2}, \rho_{2}\right) \backslash \bar{\chi}_{\rho_{2} / 2}\right)$ and, for all $\varepsilon>0$, set

$$
\begin{equation*}
\bar{\varphi}_{\varepsilon}(x)=\bar{\varphi}\left(x^{2}+\frac{\rho_{2}}{2 \varepsilon}\left(x-x^{2}\right)\right) \tag{3.5}
\end{equation*}
$$

(we intend that $\bar{\varphi}$ is extended by zero outside $B\left(x^{2}, \rho_{2}\right) \backslash \bar{\chi}_{\rho_{2} / 2}$ ). Then, it is easy to verify that $\bar{\varphi}_{\varepsilon} \in H_{S}\left(\Omega_{\varepsilon}\right)$ for $\varepsilon \in] 0, \rho_{2} / 2\left[\right.$ and $\bar{\varphi}_{\varepsilon} \equiv 0$ in $\Omega_{\varepsilon} \backslash \chi_{1}$ for $\left.\varepsilon \in\right] 0,1 / 2\left[\right.$; thus, for $0<\varepsilon<\min \left\{1 / 2, \rho_{2} / 2\right\}$, there exists $\bar{\tau}_{\varepsilon}>0$ such that $\bar{t}_{\varepsilon} \bar{\varphi}_{\varepsilon} \in M_{\varepsilon}$.
(d) For the proof of (d), it suffices to observe that, since $p>\frac{2 n}{n-2}$,

$$
\begin{equation*}
\lim _{\varepsilon \rightarrow 0} f_{\varepsilon}\left(\bar{t}_{\varepsilon} \bar{\varphi}_{\varepsilon}\right)=0 \tag{3.6}
\end{equation*}
$$

as one can easily verify by a direct computation.
(e) Let us set

$$
\begin{equation*}
F_{\varepsilon}(u)=f_{\varepsilon}^{\prime}(u)[u] \tag{3.7}
\end{equation*}
$$

(notice that $F_{\varepsilon}$ is a $C^{1}$-functional in $H_{S}\left(\Omega_{\varepsilon}\right)$ ). We shall prove that $F_{\varepsilon}^{\prime}(u) \neq 0$ for all $u \in M_{\varepsilon}$, so the assertion will follow by the implicit function theorem. In fact, if $u \in M_{\varepsilon}$, then $u \not \equiv 0$ and $F_{\varepsilon}(u)=0$, that is

$$
\int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x-\int_{\Omega_{\varepsilon}} g(x, u) u \mathrm{~d} x=0
$$

Therefore, we have

$$
\begin{aligned}
F_{\varepsilon}^{\prime}(u)[u] & =2 \int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x-\int_{\Omega_{\varepsilon}} g^{\prime}(x, u) u^{2} \mathrm{~d} x-\int_{\Omega_{\varepsilon}} g(x, u) u \mathrm{~d} x \\
& =\int_{\Omega_{\varepsilon}}\left[g(x, u) u-g^{\prime}(x, u) u^{2}\right] \mathrm{d} x
\end{aligned}
$$

(here $g^{\prime}(x, t)$ denotes the derivative of $g(x, t)$ with respect to $t$ ).
Since $g(x, t) t-g^{\prime}(x, t) t^{2}<0 \forall t \neq 0$ and since $u \not \equiv 0$, we infer that $F_{\varepsilon}^{\prime}(u)[u]<0$ and so $F_{\varepsilon}^{\prime}(u) \neq 0$.
(f) If $u \in M_{\varepsilon}$ is a critical point for $f_{\varepsilon}$ constrained on $M_{\varepsilon}$, there exists a Lagrange multiplier $\mu$ such that

$$
\begin{equation*}
f_{\varepsilon}^{\prime}(u)+\mu F_{\varepsilon}^{\prime}(u)=0 . \tag{3.8}
\end{equation*}
$$

In particular, we have

$$
\begin{equation*}
f_{\varepsilon}^{\prime}(u)[u]+\mu F_{\varepsilon}^{\prime}(u)[u]=0, \tag{3.9}
\end{equation*}
$$

which implies $\mu=0$ since $f_{\varepsilon}^{\prime}(u)[u]=0$ (because $u \in M_{\varepsilon}$ ) and $F_{\varepsilon}^{\prime}(u)[u] \neq 0$. Therefore, $f_{\varepsilon}^{\prime}(u)=0$.
Thus, finding nontrivial critical points for $f_{\varepsilon}$ is equivalent to finding critical points for $f_{\varepsilon}$ constrained on $M_{\varepsilon}$. The compactness property proved in the following lemma plays an important role to find critical points for $f_{\varepsilon}$ constrained on $M_{\varepsilon}$.

Lemma 3.2. Let $\varepsilon>0$ be such that $M_{\varepsilon} \neq \emptyset$ and $\left(u_{i}\right)_{i}$ be a sequence in $M_{\varepsilon}$. The following properties hold.
(a) If $\sup _{i \in \mathbb{N}} f_{\varepsilon}\left(u_{i}\right)<+\infty$, then the sequence $\left(u_{i}\right)_{i}$ is bounded in $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$.
(b) Let us set $F_{\varepsilon}(u)=f_{\varepsilon}^{\prime}(u)[u]$; if $u_{i} \rightharpoonup u$ weakly in $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$ and there exists a sequence $\left(\mu_{i}\right)_{i}$ in $\mathbb{R}$ such that

$$
\begin{equation*}
f_{\varepsilon}^{\prime}\left(u_{i}\right)+\mu_{i} F_{\varepsilon}^{\prime}\left(u_{i}\right) \longrightarrow 0 \quad \text { in } H^{-1}\left(\Omega_{\varepsilon}\right) \tag{3.10}
\end{equation*}
$$

then $\lim _{i \rightarrow \infty} \mu_{i}=0, u \in M_{\varepsilon}$ and $u_{i} \rightarrow u$ in $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$.
(c) The functional $f_{\varepsilon}$ constrained on $M_{\varepsilon}$ satisfies the Palais-Smale condition at any level $c \in \mathbb{R}$, i.e. every sequence $\left(u_{i}\right)_{i}$ in $M_{\varepsilon}$, such that

$$
\begin{equation*}
\lim _{i \rightarrow \infty} f_{\varepsilon}\left(u_{i}\right)=c \quad \text { and } \quad \operatorname{grad}_{M_{\varepsilon}} f_{\varepsilon}\left(u_{i}\right) \rightarrow 0 \quad \text { in } H^{-1}\left(\Omega_{\varepsilon}\right), \tag{3.11}
\end{equation*}
$$

is relatively compact in $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$.
Proof. (a) Since $u_{i} \in M_{\varepsilon}$, taking into account the definition of $G(x, t)$, we have

$$
\begin{aligned}
f_{\varepsilon}\left(u_{i}\right) & =\frac{1}{2} \int_{\Omega_{\varepsilon}}\left|D u_{i}\right|^{2} \mathrm{~d} x-\int_{\Omega_{\varepsilon}} G\left(x, u_{i}\right) \mathrm{d} x \\
& \geqslant \frac{1}{2} \int_{\Omega_{\varepsilon}}\left|D u_{i}\right|^{2} \mathrm{~d} x-\frac{1}{2} \int_{\Omega_{\varepsilon} \backslash \bar{x}_{1}} g\left(x, u_{i}\right) u_{i} \mathrm{~d} x-\frac{1}{p} \int_{\Omega_{\varepsilon} \cap x_{1}}\left|u_{i}\right|^{p} \mathrm{~d} x \\
& =\left(\frac{1}{2}-\frac{1}{p}\right) \int_{\Omega_{\varepsilon}}\left|D u_{i}\right|^{2} \mathrm{~d} x-\left(\frac{1}{2}-\frac{1}{p}\right) \int_{\Omega_{\varepsilon} \backslash \bar{x}_{1}} g\left(x, u_{i}\right) u_{i} \mathrm{~d} x .
\end{aligned}
$$

It follows that

$$
\begin{equation*}
\sup _{i \in \mathbb{N}}\left\{\int_{\Omega_{\varepsilon}}\left|D u_{i}\right|^{2} \mathrm{~d} x-\int_{\Omega_{\varepsilon} \backslash \bar{x}_{1}} g\left(x, u_{i}\right) u_{i} \mathrm{~d} x\right\}<+\infty . \tag{3.12}
\end{equation*}
$$

Hence (3.12) and (2.12) imply sup $i_{i \in \mathbb{N}} \int_{\Omega_{\varepsilon}}\left|D u_{i}\right|^{2} \mathrm{~d} x<+\infty$.
(b) First, let us prove that $u \not \equiv 0$. Notice that

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon} \backslash \bar{x}_{1}}\left|u_{i}-u\right|^{2} \mathrm{~d} x=0 \tag{3.13}
\end{equation*}
$$

moreover, since $\varepsilon>0$ and $u_{i} \in H_{S}\left(\Omega_{\varepsilon}\right)$,

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon} \cap \chi_{1}}\left|u_{i}-u\right|^{p} \mathrm{~d} x=0 \tag{3.14}
\end{equation*}
$$

Notice that $u_{i} \in M_{\varepsilon}$ implies

$$
\begin{equation*}
\int_{\Omega_{\varepsilon} \backslash \bar{\chi}_{1}}\left[\left|D u_{i}\right|^{2}-g\left(x, u_{i}\right) u_{i}\right] \mathrm{d} x+\int_{\Omega_{\varepsilon} \cap \chi_{1}}\left[\left|D u_{i}\right|^{2}-\left|u_{i}\right|^{p}\right] \mathrm{d} x=0 . \tag{3.15}
\end{equation*}
$$

Let us observe that we must have

$$
\begin{equation*}
\int_{\Omega_{\varepsilon} \cap \chi_{1}}\left|u_{i}\right|^{p} \mathrm{~d} x>0 \quad \forall i \in \mathbb{N}, \tag{3.16}
\end{equation*}
$$

otherwise, since $u_{i} \not \equiv 0$ in $\Omega_{\varepsilon}$, we should have

$$
\int_{\Omega_{\varepsilon} \backslash \bar{x}_{1}}\left[\left|D u_{i}\right|^{2}-g\left(x, u_{i}\right) u_{i}\right] \mathrm{d} x>0
$$

because of the choice of $t_{0}$ (see (2.10)), which contradicts (3.15).
Since

$$
\begin{equation*}
\int_{\Omega_{\varepsilon} \backslash \bar{x}_{1}}\left[|D u|^{2}-g(x, u) u\right] \mathrm{d} x \geqslant 0 \quad \forall u \in H_{0}^{1,2}\left(\Omega_{\varepsilon}\right), \tag{3.17}
\end{equation*}
$$

we infer from (3.15)

$$
\int_{\Omega_{\varepsilon} \cap \chi_{1}}\left|u_{i}\right|^{p} \mathrm{~d} x \geqslant \int_{\Omega_{\varepsilon} \cap \chi_{1}}\left|D u_{i}\right|^{2} \mathrm{~d} x .
$$

On the other hand, as $\varepsilon>0$ and $u_{i} \in H_{S}\left(\Omega_{\varepsilon}\right)$, there exists a constant $\bar{c}>0$ such that

$$
\begin{equation*}
\int_{\Omega_{\varepsilon} \cap \chi_{1}}|D u|^{2} \mathrm{~d} x \geqslant \bar{c}\left(\int_{\Omega_{\varepsilon} \cap \chi_{1}}|u|^{p} \mathrm{~d} x\right)^{2 / p} \quad \forall u \in H_{S}\left(\Omega_{\varepsilon}\right) . \tag{3.18}
\end{equation*}
$$

Hence we get

$$
\int_{\Omega_{\varepsilon} \cap \chi_{1}}\left|u_{i}\right|^{p} \mathrm{~d} x \geqslant \int_{\Omega_{\varepsilon} \cap \chi_{1}}\left|D u_{i}\right|^{2} \mathrm{~d} x \geqslant \bar{c}\left(\int_{\Omega_{\varepsilon} \cap \chi_{1}}\left|u_{i}\right|^{p} \mathrm{~d} x\right)^{2 / p} \quad \forall i \in \mathbb{N},
$$

which, because of (3.16), implies

$$
\inf _{i \in \mathbb{N}} \int_{\Omega_{\varepsilon} \cap \chi_{1}}\left|u_{i}\right|^{p} \mathrm{~d} x>0 .
$$

Taking into account (3.14), it follows that

$$
\begin{equation*}
\int_{\Omega_{\varepsilon} \cap X_{1}}|u|^{p} \mathrm{~d} x>0 \tag{3.19}
\end{equation*}
$$

Notice that, as $u_{i} \in M_{\varepsilon}$, (3.10) implies

$$
\begin{equation*}
\lim _{i \rightarrow \infty} u_{i} F_{\varepsilon}^{\prime}\left(u_{i}\right)\left[u_{i}\right]=0 . \tag{3.20}
\end{equation*}
$$

Moreover, $u_{i} \in M_{\varepsilon}$ implies

$$
\begin{equation*}
F_{\varepsilon}^{\prime}\left(u_{i}\right)\left[u_{i}\right]=2 \int_{\Omega_{\varepsilon}}\left|D u_{i}\right|^{2} \mathrm{~d} x-\int_{\Omega_{\varepsilon}} g^{\prime}\left(x, u_{i}\right) u_{i}^{2} \mathrm{~d} x-\int_{\Omega_{\varepsilon}} g\left(x, u_{i}\right) u_{i} \mathrm{~d} x=\int_{\Omega_{\varepsilon}}\left[g\left(x, u_{i}\right) u_{i}-g^{\prime}\left(x, u_{i}\right) u_{i}^{2}\right] \mathrm{d} x . \tag{3.21}
\end{equation*}
$$

Hence, from (3.13) and (3.14) we infer that

$$
\begin{equation*}
\lim _{i \rightarrow \infty} F_{\varepsilon}^{\prime}\left(u_{i}\right)\left[u_{i}\right]=\int_{\Omega_{\varepsilon}}\left[g(x, u) u-g^{\prime}(x, u) u^{2}\right] \mathrm{d} x . \tag{3.22}
\end{equation*}
$$

Notice that

$$
\int_{\Omega_{\varepsilon}}\left[g(x, u) u-g^{\prime}(x, u) u^{2}\right] \mathrm{d} x<0
$$

because $g(x, t) t-g^{\prime}(x, t) t^{2}<0 \forall t \neq 0$ and $u \not \equiv 0$ in $\Omega_{\varepsilon}$ (as (3.19) holds). Taking into account (3.20), it follows that

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \mu_{i}=0 . \tag{3.23}
\end{equation*}
$$

Using again (3.10), we obtain

$$
\begin{equation*}
\lim _{i \rightarrow \infty}\left\{f_{\varepsilon}^{\prime}\left(u_{i}\right)\left[u-u_{i}\right]+\mu_{i} F_{\varepsilon}^{\prime}\left(u_{i}\right)\left[u-u_{i}\right]\right\}=0, \tag{3.24}
\end{equation*}
$$

which, taking into account (3.13), (3.14), (3.20), (3.23) and the weak convergence of $u_{i}$, implies

$$
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon}}\left|D u_{i}\right|^{2} \mathrm{~d} x=\int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x
$$

Thus, $u_{i} \rightarrow u$ strongly in $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$ and $u \in M_{\varepsilon}$.
(c) Property (a) implies that every Palais-Smale sequence $\left(u_{i}\right)_{i}$ is bounded in $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$; hence, up to a subsequence, it converges weakly in $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$; then, property (b) guarantees the strong convergence in $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$ to a function $u \in M_{\varepsilon}$.

Lemma 3.3. Let $\left(\varepsilon_{i}\right)_{i}$ be a sequence of positive numbers and $\left(u_{i}\right)_{i}$ a sequence of functions in $H_{S}\left(\Omega_{\varepsilon_{i}}\right)$ such that $f_{\varepsilon_{i}}^{\prime}\left(u_{i}\right)=0$ and $u_{i} \not \equiv 0$ in $\Omega_{\varepsilon_{i}}$ for all $i \in \mathbb{N}$.

If $\lim _{i \rightarrow \infty} f_{\varepsilon_{i}}\left(u_{i}\right)=0$, then
(a) $\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i}}}\left|D u_{i}\right|^{2} \mathrm{~d} x=0$,
(b) $\lim _{i \rightarrow \infty} \varepsilon_{i}=0$,
(c) $\lim _{i \rightarrow \infty} \sup \left\{\left|u_{i}(x)\right|: x \in \Omega_{\varepsilon_{i}} \backslash \chi_{\rho}\right\}=0 \forall \rho>0$.

Proof. (a) Clearly, it suffices to prove that there exists a constant $\bar{c}>0$ for which

$$
\begin{equation*}
f_{\varepsilon}(u) \geqslant \bar{c} \int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x \tag{3.25}
\end{equation*}
$$

for all $\varepsilon>0$ and for all $u \in H_{S}\left(\Omega_{\varepsilon}\right)$ such that $f_{\varepsilon}^{\prime}(u)=0$.
If $f_{\varepsilon}^{\prime}(u)=0$, arguing as in the proof of Lemma 3.2, we have

$$
\begin{align*}
f_{\varepsilon}(u) & \geqslant \frac{1}{2} \int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x-\frac{1}{2} \int_{\Omega_{\varepsilon} \backslash \bar{\chi}_{1}} g(x, u) u \mathrm{~d} x-\frac{1}{p} \int_{\Omega_{\varepsilon} \cap \chi_{1}}|u|^{p} \mathrm{~d} x \\
& =\left(\frac{1}{2}-\frac{1}{p}\right)\left\{\int_{\Omega_{\varepsilon} \backslash \bar{\chi}_{1}}\left[|D u|^{2}-g(x, u) u\right] \mathrm{d} x+\int_{\Omega_{\varepsilon} \cap \chi_{1}}|D u|^{2} \mathrm{~d} x\right\} . \tag{3.26}
\end{align*}
$$

Hence, the existence of a constant $\bar{c}>0$, such that (3.25) holds, follows easily from (2.12).
(b) Arguing by contradiction, assume that, up to a subsequence, $\inf _{i \in \mathbb{N}} \varepsilon_{i}>0$ and choose $\left.\bar{\varepsilon} \in\right] 0, \inf _{i \in \mathbb{N}} \varepsilon_{i}$ [. Thus, $u_{i} \in H_{S}\left(\Omega_{\bar{\varepsilon}}\right)$ for all $i \in \mathbb{N}$. Since $\bar{\varepsilon}>0$, there exists a constant $\bar{c}_{\bar{\varepsilon}}>0$ such that

$$
\begin{equation*}
\int_{\Omega_{\bar{\varepsilon}} \cap \chi_{1}}|D u|^{2} \mathrm{~d} x \geqslant \bar{c}_{\bar{\varepsilon}}\left(\int_{\Omega_{\bar{\varepsilon}} \cap X_{1}}|u|^{p} \mathrm{~d} x\right)^{2 / p} \quad \forall u \in H_{S}\left(\Omega_{\bar{\varepsilon}}\right) . \tag{3.27}
\end{equation*}
$$

Hence, property (a) implies

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \int_{\Omega_{\bar{\varepsilon}} \cap x_{1}}\left|u_{i}\right|^{p} \mathrm{~d} x=0 \tag{3.28}
\end{equation*}
$$

On the other hand, we have $f_{\bar{\varepsilon}}^{\prime}\left(u_{i}\right)\left[u_{i}\right]=0$, that is

$$
\begin{equation*}
\int_{\Omega_{\bar{\varepsilon}} \cap X_{1}}\left[\left|D u_{i}\right|^{2}-\left|u_{i}\right|^{p}\right] \mathrm{d} x+\int_{\Omega_{\bar{\varepsilon}} \backslash \bar{\chi}_{1}}\left[\left|D u_{i}\right|^{2}-g\left(x, u_{i}\right) u_{i}\right] \mathrm{d} x=0 . \tag{3.29}
\end{equation*}
$$

First, let us remark that (3.29) implies

$$
\begin{equation*}
\int_{\Omega_{\bar{\varepsilon}} \cap \chi_{1}}\left|u_{i}\right|^{p} \mathrm{~d} x>0 \quad \forall i \in \mathbb{N} \tag{3.30}
\end{equation*}
$$

otherwise, as $u_{i} \not \equiv 0$ in $\Omega_{\bar{\varepsilon}}$, we should have (because of (2.12))

$$
\int_{\Omega_{\bar{\varepsilon}} \backslash \bar{x}_{1}}\left[\left|D u_{i}\right|^{2}-g\left(x, u_{i}\right) u_{i}\right] \mathrm{d} x>0
$$

and so (3.29) cannot hold.
Moreover, from (3.29) and (2.12) we infer that

$$
\begin{equation*}
\int_{\Omega_{\bar{\varepsilon}} \cap X_{1}}\left|u_{i}\right|^{p} \mathrm{~d} x \geqslant \int_{\Omega_{\bar{\varepsilon}} \cap X_{1}}\left|D u_{i}\right|^{2} \mathrm{~d} x \quad \forall i \in \mathbb{N} . \tag{3.31}
\end{equation*}
$$

Therefore, taking into account (3.27), (3.30) and (3.31), we get

$$
\begin{equation*}
\inf _{i \in \mathbb{N}} \int_{\Omega_{\bar{\varepsilon}} \cap \chi_{1}}\left|u_{i}\right|^{p} \mathrm{~d} x>0 \tag{3.32}
\end{equation*}
$$

which contradicts (3.28).
(c) For all $\rho>0$, let us consider the cylinder

$$
C_{\rho}=\left\{x=\left(x_{1}, \ldots, x_{n}\right) \in \mathbb{R}^{n}: \sum_{i=1}^{n-1} x_{i}^{2} \leqslant \rho^{2}\right\} .
$$

Since the subspace of the radial functions in $H^{1}\left(\Omega \backslash C_{\rho}\right)$ is embedded in $L^{q}\left(\Omega \backslash C_{\rho}\right)$ for all $\rho>0$ and $q \geqslant 1$, property (a) implies

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i}} \backslash C_{\rho}}\left|u_{i}\right|^{q} \mathrm{~d} x=0 \quad \forall q \geqslant 1, \forall \rho>0 \tag{3.33}
\end{equation*}
$$

Now, let us introduce the function $w_{i}$ defined by

$$
w_{i}(x)=\frac{1}{n(n-2) \omega_{n}} \int_{\Omega_{\varepsilon_{i}}} \frac{\left|g\left(y, u_{i}(y)\right)\right|}{|x-y|^{n-2}} \mathrm{~d} y
$$

where $\omega_{n}$ is the measure of the unit sphere of $\mathbb{R}^{n}$. It is well known that $w_{i}$ solves the equation

$$
\Delta w_{i}(x)+\left|g\left(x, u_{i}(x)\right)\right|=0
$$

moreover, we have $w_{i} \geqslant 0$ on $\partial \Omega_{\varepsilon_{i}}$, which implies

$$
\begin{equation*}
w_{i}(x) \geqslant\left|u_{i}(x)\right| \quad \forall x \in \Omega_{\varepsilon_{i}} . \tag{3.34}
\end{equation*}
$$

Now, let us prove that

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \sup \left\{w_{i}(x): x \in \Omega \backslash C_{\rho}\right\}=0 \quad \forall \rho>0 \tag{3.35}
\end{equation*}
$$

For all $x \in \Omega \backslash C_{\rho}$, we write $w_{i}$ as

$$
\begin{equation*}
w_{i}(x)=\frac{1}{n(n-2) \omega_{n}}\left[\int_{\Omega_{\varepsilon_{i} \backslash B(x, \rho / 2)}} \frac{\left|g\left(y, u_{i}(y)\right)\right|}{|x-y|^{n-2}} \mathrm{~d} y+\int_{\Omega_{\varepsilon_{i}} \cap B(x, \rho / 2)} \frac{\left|g\left(y, u_{i}(y)\right)\right|}{|x-y|^{n-2}} \mathrm{~d} y\right] \tag{3.36}
\end{equation*}
$$

The first integral in (3.36) can be estimated as follows:

$$
\begin{equation*}
\int_{\Omega_{\varepsilon_{i}} \backslash B(x, \rho / 2)} \frac{\left|g\left(y, u_{i}(y)\right)\right|}{|x-y|^{n-2}} \mathrm{~d} y \leqslant\left(\frac{2}{\rho}\right)^{n-2} \int_{\Omega_{\varepsilon_{i}}}\left|g\left(y, u_{i}(y)\right)\right| \mathrm{d} y \tag{3.37}
\end{equation*}
$$

As $f_{\varepsilon_{i}}^{\prime}\left(u_{i}\right)=0$, property (a) implies

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i}}} g\left(x, u_{i}\right) u_{i} \mathrm{~d} x=0 \tag{3.38}
\end{equation*}
$$

Since

$$
\begin{equation*}
|g(x, t)| \leqslant g(x, t) t+g(x, 1) \quad \forall x \in \Omega, \forall t \in \mathbb{R}, \tag{3.39}
\end{equation*}
$$

taking into account the definition of $g(x, t)$, we easily infer that

$$
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i}}}\left|g\left(y, u_{i}(y)\right)\right| \mathrm{d} y=0
$$

which, by (3.37), implies

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i} \backslash B(x, \rho / 2)}} \frac{\left|g\left(y, u_{i}(y)\right)\right|}{|x-y|^{n-2}} \mathrm{~d} y=0 \tag{3.40}
\end{equation*}
$$

uniformly with respect to $x \in \Omega \backslash C_{\rho}$.
In order to deal with the second integral in (3.36), let us remark that, since $x \in \Omega \backslash C_{\rho}$,

$$
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i}} \cap B(x, \rho / 2)}\left|g\left(y, u_{i}(y)\right)\right|^{q} \mathrm{~d} y=0 \quad \forall q \geqslant 1, \forall \rho>0
$$

because of (3.33). Since $\Omega_{\varepsilon_{i}} \cap B(x, \rho / 2) \subset \Omega \backslash C_{\rho / 2}$ for all $x \in \Omega \backslash C_{\rho}$, for $q>\frac{n}{2}$ we obtain

$$
\int_{\Omega_{\varepsilon_{i}} \cap B(x, \rho / 2)} \frac{\left|g\left(y, u_{i}(y)\right)\right|}{|x-y|^{n-2}} \mathrm{~d} y \leqslant c(p, q)\left(\int_{\Omega_{\varepsilon_{i}} \backslash C_{\rho / 2}}\left|g\left(y, u_{i}(y)\right)\right|^{q} \mathrm{~d} y\right)^{1 / q} \quad \forall x \in \Omega \backslash C_{\rho},
$$

where $c(p, q)$ is a suitable constant depending only on $p$ and $q$. Taking into account (3.33), it follows that

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i}} \cap B(x, \rho / 2)} \frac{\left|g\left(y, u_{i}(y)\right)\right|}{|x-y|^{n-2}} \mathrm{~d} y=0 \tag{3.41}
\end{equation*}
$$

uniformly with respect to $x \in \Omega \backslash C_{\rho}$. Hence, (3.35) follows from (3.36), (3.40) and (3.41). Notice that, since $x^{1}$ and $x^{2}$ do not belong to $\bar{\Omega}$, (3.34) and (3.35) imply, in particular, that $u_{i} \rightarrow 0$ uniformly on the boundary of $\Omega \backslash \bar{\chi}_{1}$. Therefore, taking into account the definition of $g(x, t)$ for $x \in \Omega \backslash \bar{\chi}_{1}$, it follows that $u_{i} \rightarrow 0$ uniformly in $\Omega \backslash \bar{\chi}_{1}$. Thus, property (c) is completely proved.

Corollary 3.4. There exists a positive constant $\bar{c}(\Omega, p)$ (depending only on $\Omega$ and p) such that, if $u \in H_{S}\left(\Omega_{\varepsilon}\right)$ is a critical point for $f_{\varepsilon}$ and $f_{\varepsilon}(u) \leqslant \bar{c}(\Omega, p)$, then
(a) $|u(x)| \leqslant t_{0} \forall x \in \Omega_{\varepsilon} \backslash \bar{\chi}_{1}$,
(b) $u$ solves problem $P\left(\Omega_{\varepsilon}\right)$ (provided $u \not \equiv 0$ in $\Omega_{\varepsilon}$ ).

The proof follows easily from property (c) of Lemma 3.3.
Proposition 3.5. For all $\varepsilon>0$, the minimum of the functional $f_{\varepsilon}$ constrained on $M_{\varepsilon}$ is achieved. Moreover,
(a) the minimizing functions have constant sign;
(b) there exists $\varepsilon_{1}>0$ such that, for all $\left.\varepsilon \in\right] 0, \varepsilon_{1}\left[\right.$, the minimizing functions solve problem $P\left(\Omega_{\varepsilon}\right)$.

Proof. The existence of the minimum of $f_{\varepsilon}$ on $M_{\varepsilon}$ follows from Lemma 3.2 and (b) of Lemma 3.1. Property (a) is a consequence of Lemma 3.1. In fact, if $u \in M_{\varepsilon}$ is a minimizing function for $f_{\varepsilon}$ on $M_{\varepsilon}$ and assume, for example, that $u^{+} \not \equiv 0$, then we must have $u^{-} \equiv 0$; otherwise, $u^{+}$and $u^{-}$belong to $M_{\varepsilon}$ and, by (b) of Lemma 3.1, $f_{\varepsilon}\left(u^{ \pm}\right)>$ $\inf _{M_{\varepsilon}} f_{\varepsilon}>0$; it follows that

$$
f_{\varepsilon}(u)=f_{\varepsilon}\left(u^{+}\right)+f_{\varepsilon}\left(u^{-}\right)>f_{\varepsilon}\left(u^{+}\right)
$$

which is a contradiction, since $f_{\varepsilon}(u)=\inf _{M_{\varepsilon}} f_{\varepsilon}$.
Property (b) follows easily from Corollary 3.4, taking into account (d) of Lemma 3.1.
Remark 3.6. When $2<p<\frac{2 n}{n-2}$, since $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$ is compactly embedded in $L^{p}\left(\Omega_{\varepsilon}\right)$, a positive solution of problem $P\left(\Omega_{\varepsilon}\right)$ can be easily obtained for all $\varepsilon \geqslant 0$ by minimizing the functional

$$
\tilde{f}(u)=\frac{1}{2} \int_{\Omega}|D u|^{2} \mathrm{~d} x-\frac{1}{p} \int_{\Omega}|u|^{p} \mathrm{~d} x
$$

constrained on the manifold

$$
\tilde{M}_{\varepsilon}=\left\{u \in H_{S}\left(\Omega_{\varepsilon}\right): u \not \equiv 0, \int_{\Omega_{\varepsilon}}|D u|^{2} \mathrm{~d} x=\int_{\Omega_{\varepsilon}}|u|^{p} \mathrm{~d} x\right\} .
$$

On the contrary, when $p \geqslant \frac{2 n}{n-2}$, the existence of the minimum of $\tilde{f}$ on $\widetilde{M}_{\varepsilon}$ is not guaranteed. Indeed, if $\Omega_{\varepsilon}$ meets the $x_{n}$-axis, it is easy to verify that, for all $\varepsilon \geqslant 0$,
(a) if $p>\frac{2 n}{n-2}$, then

$$
\begin{equation*}
\inf _{\widetilde{\mathbb{M}}_{\varepsilon}} \tilde{f}=0 \tag{3.42}
\end{equation*}
$$

which, of course, implies that the minimum does not exist;
(b) if $p=\frac{2 n}{n-2}$, then

$$
\begin{equation*}
\inf _{\widetilde{M}_{\varepsilon}} \tilde{f}=S>0 \tag{3.43}
\end{equation*}
$$

where $S$ denotes the best Sobolev constant; as it is well known (see [4,21], etc.), the infimum $S$ cannot be achieved for any bounded domain $\Omega_{\varepsilon}$.

Hence, for $p \geqslant \frac{2 n}{n-2}$ the problem cannot be solved by minimization. For $p=\frac{2 n}{n-2}$ and $\varepsilon>0$, positive solutions of $P\left(\Omega_{\varepsilon}\right)$ are obtained in [16] as local minimum points for $\tilde{f}$ constrained on $\widetilde{M}_{\varepsilon}$. On the contrary, this approach does not work any more for $p>\frac{2 n}{n-2}$, since in this case, if $\Omega_{\varepsilon}$ meets the $x_{n}$-axis, $\tilde{f}$ constrained on $\widetilde{M}_{\varepsilon}$ cannot have any local minimum point. In fact, for all $u \in \widetilde{M}_{\varepsilon}$, we can find a sequence $\left(u_{i}\right)_{i}$ in $\widetilde{M}_{\varepsilon}$, which converges to $u$ in $H_{0}^{1,2}\left(\Omega_{\varepsilon}\right)$ and in $L^{p}\left(\Omega_{\varepsilon}\right)$ and satisfies

$$
\tilde{f}\left(u_{i}\right)<\tilde{f}(u) \quad \forall i \in \mathbb{N}
$$

Such a sequence $\left(u_{i}\right)_{i}$ can be obtained as follows. Let $\tilde{x}^{2}=\left(0, \ldots, 0, \tilde{x}_{n}^{2}\right)$, with $\tilde{x}_{n}^{2} \notin\left[x_{n}^{1}, x_{n}^{3}\right]$, be a point of the $x_{n}$-axis, which belongs to $\Omega$; let $z \in C_{0}^{\infty}(B(0,1)), z \not \equiv 0$, be a fixed function having radial symmetry with respect to the origin; for all $\rho>0$, let us set

$$
z_{\rho}(x)=z\left(\frac{x-\tilde{x}^{2}}{\rho}\right)
$$

Notice that

$$
\tilde{u}_{\rho}=\left(\frac{\left\|D z_{\rho}\right\|_{2}^{2}}{\left\|z_{\rho}\right\|_{p}^{p}}\right)^{1 /(p-2)} z_{\rho} \in \tilde{M}_{\varepsilon} \quad \forall \varepsilon \geqslant 0
$$

for $\rho>0$ small enough; moreover, $\lim _{\rho \rightarrow 0} \tilde{f}\left(\tilde{u}_{\rho}\right)=0$ for all $p>\frac{2 n}{n-2}$ (which, in particular, implies (3.42)). Now, for all $i \in \mathbb{N}$, set

$$
u_{i, \rho}=\left(1-\frac{1}{i}\right)^{1 / p} u+\left(\frac{1}{i}\right)^{1 / p} \frac{\|u\|_{p}}{\left\|z_{\rho}\right\|_{p}} z_{\rho} .
$$

One can verify that

$$
\lim _{\rho \rightarrow 0}\left\|u_{i, \rho}\right\|_{p}=\|u\|_{p} \quad \forall i \in \mathbb{N}
$$

and

$$
\lim _{\rho \rightarrow 0}\left\|D u_{i, \rho}\right\|_{2}^{2}=\left(1-\frac{1}{i}\right)^{2 / p}\|D u\|_{2}^{2}<\|D u\|_{2}^{2} \quad \forall i \in \mathbb{N},
$$

where the strict inequality holds because $u \not \equiv 0$ in $\Omega_{\varepsilon}$. It follows that there exists a sequence of positive numbers $\rho_{i} \rightarrow 0$ such that, if we set

$$
u_{i}=\left(\frac{\left\|D u_{i, \rho_{i}}\right\|_{2}^{2}}{\left\|u_{i, \rho_{i}}\right\|_{p}^{p}}\right)^{1 /(p-2)} u_{i, \rho_{i}} \quad \forall i \in \mathbb{N},
$$

then the sequence $\left(u_{i}\right)_{i}$ satisfies the desired properties.
Proposition 3.7. Let $p>\frac{2 n}{n-2}$ and $\Omega$ be a bounded domain satisfying the same assumptions as in Theorem 2.1. Then, for all positive integer $k$, there exists $\varepsilon_{k}>0$ such that, for all $\left.\varepsilon \in\right] 0, \varepsilon_{k}\left[\right.$, the functional $f_{\varepsilon}$ has at least $2 k$ nontrivial critical points $\pm u_{1, \varepsilon}, \ldots, \pm u_{k, \varepsilon}$. Moreover, we have

$$
\begin{equation*}
\lim _{\varepsilon \rightarrow 0} f_{\varepsilon}\left(u_{i, \varepsilon}\right)=0 \quad \forall i=1, \ldots, k \tag{3.44}
\end{equation*}
$$

Proof. Since $x^{2} \in \Omega$, there exist $k$ distinct points $\bar{x}^{1}, \ldots, \bar{x}^{k}$ on the $x_{n}$-axis, which belong to $\Omega$ and satisfy

$$
\bar{x}^{i}=\left(0, \ldots, 0, \bar{x}_{n}^{i}\right) \quad \text { with } x_{n}^{1}<\bar{x}_{n}^{i}<x_{n}^{3} \forall i=1, \ldots, k .
$$

Set

$$
C_{1}=\left\{x=\left(x_{1}, \ldots, x_{n}\right) \in \mathbb{R}^{n}: \sum_{i=1}^{n-1} x_{i}^{2} \leqslant 1\right\}
$$

and choose a function $\varphi \in H_{0}^{1,2}\left(B(0,2) \backslash C_{1}\right), \varphi \not \equiv 0$, having radial symmetry with respect to the $x_{n}$-axis.
For all $i=1, \ldots, k$ and $\varepsilon>0$, let $\varphi_{i, \varepsilon}$ be the function defined by

$$
\varphi_{i, \varepsilon}(x)=\varphi\left(\frac{x-\bar{x}_{i}}{\varepsilon}\right)
$$

(here we intend that $\varphi$ is extended by zero outside $\left.B(0,2) \backslash C_{1}\right)$.
Since $\bar{x}^{1}, \ldots, \bar{x}^{k}$ are distinct points in $\Omega$, there exists $\varepsilon_{k}>0$ such that, for all $\left.\varepsilon \in\right] 0, \varepsilon_{k}\left[\right.$, the functions $\varphi_{1, \varepsilon}, \ldots, \varphi_{k, \varepsilon}$ belong to $H_{S}\left(\Omega_{\varepsilon}\right)$ and have disjoint supports. Notice that, for all $\sigma=\left(\sigma_{1}, \ldots, \sigma_{k}\right) \in \mathbb{R}^{k}$, such that $\sum_{i=1}^{k} \sigma_{i}^{2}=1$, there exists a unique positive number $\tau_{\varepsilon}(\sigma)$ such that

$$
\tau_{\varepsilon}(\sigma) \sum_{i=1}^{k} \sigma_{i} \varphi_{i, \varepsilon} \in M_{\varepsilon}
$$

moreover, $\tau_{\varepsilon}(\sigma)$ depends continuously on $\sigma$. In fact, we have $\sum_{i=1}^{k} \sigma_{i} \varphi_{i, \varepsilon} \not \equiv 0$ because $\varphi \not \equiv 0, \varphi_{1, \varepsilon}, \ldots, \varphi_{k, \varepsilon}$ have disjoint supports and $\sum_{i=1}^{k} \sigma_{i}^{2}=1$; a direct computation shows that

$$
\begin{equation*}
\tau_{\varepsilon}(\sigma)=\left(\frac{\left\|\sum_{i=1}^{k} \sigma_{i} D \varphi_{i, \varepsilon}\right\|_{2}^{2}}{\left\|\sum_{i=1}^{k} \sigma_{i} \varphi_{i, \varepsilon}\right\|_{p}^{p}}\right)^{1 /(p-2)}, \tag{3.45}
\end{equation*}
$$

which satisfies all the properties above described.
Now, let us introduce the following subset of $M_{\varepsilon}$

$$
\begin{equation*}
S_{k}^{\varepsilon}=\left\{\tau_{\varepsilon}(\sigma) \sum_{i=1}^{k} \sigma_{i} \varphi_{i, \varepsilon}: \sigma=\left(\sigma_{1}, \ldots, \sigma_{k}\right) \in \mathbb{R}^{k}, \sum_{i=1}^{k} \sigma_{i}^{2}=1\right\} . \tag{3.46}
\end{equation*}
$$

Notice that $S_{k}^{\varepsilon}$ is radially diffeomorphic to the unit sphere of $\mathbb{R}^{k}$, as follows easily from (3.45). Hence, since $f_{\varepsilon}$ constrained on $M_{\varepsilon}$ satisfies the Palais-Smale condition (see Lemma 3.2), well known multiplicity results of the critical points theory for even functionals (see, for example, [9]) guarantee that there exist at least $k$ pairs $\pm u_{1, \varepsilon}, \ldots, \pm u_{k, \varepsilon}$ of critical points for $f_{\varepsilon}$ constrained on $M_{\varepsilon}$, which satisfy

$$
\begin{equation*}
f_{\varepsilon}\left(u_{i, \varepsilon}\right) \leqslant \sup _{S_{k}^{\varepsilon}} f_{\varepsilon} \quad \forall i=1, \ldots, k \tag{3.47}
\end{equation*}
$$

Notice that the functions $\pm u_{1, \varepsilon}, \ldots, \pm u_{k, \varepsilon}$ are nontrivial critical points for $f_{\varepsilon}$ because of Lemma 3.1. Finally, let us remark that

$$
\begin{equation*}
\lim _{\varepsilon \rightarrow 0} \sup _{S_{k}^{\varepsilon}} f_{\varepsilon}=0, \tag{3.48}
\end{equation*}
$$

as one can easily verify taking into account that

$$
\begin{equation*}
\lim _{\varepsilon \rightarrow 0} \frac{\left\|D \varphi_{i, \varepsilon}\right\|_{2}}{\left\|\varphi_{i, \varepsilon}\right\|_{p}}=0 \quad \forall i=1, \ldots, k \tag{3.49}
\end{equation*}
$$

(indeed, $\left\|D \varphi_{i, \varepsilon}\right\|_{2}$ and $\left\|\varphi_{i, \varepsilon}\right\|_{p}$ do not depend on $i=1, \ldots, k$ ).
Thus, (3.44) follows from (3.47) and (3.48).
The following proposition states a general property of the solutions of problem $P(\Omega)$, that we shall use to describe the behaviour of the solutions of $P\left(\Omega_{\varepsilon}\right)$ as $\varepsilon \rightarrow 0$.

Proposition 3.8. Let $\Omega$ be a bounded domain of $\mathbb{R}^{n}$ and $u$ be a solution of problem $P(\Omega)$ with $p>2$. Let $\lambda_{1}$ be the first eigenvalue of the Laplace operator $-\Delta$ in $H_{0}^{1,2}(\Omega)$. Then,

$$
\begin{equation*}
u^{+} \not \equiv 0 \quad \text { implies } \quad \sup _{\Omega} u^{+} \geqslant \lambda_{1}^{1 /(p-2)} \tag{3.50}
\end{equation*}
$$

and

$$
\begin{equation*}
u^{-} \not \equiv 0 \quad \text { implies } \quad \sup _{\Omega} u^{-} \geqslant \lambda_{1}^{1 /(p-2)} . \tag{3.51}
\end{equation*}
$$

Proof. Since $u$ solves problem $P(\Omega)$, we have in particular

$$
\begin{equation*}
\int_{\Omega}\left|D u^{+}\right|^{2} \mathrm{~d} x=\int_{\Omega}\left(u^{+}\right)^{p} \mathrm{~d} x \tag{3.52}
\end{equation*}
$$

On the other hand, since $u^{+} \in H_{0}^{1,2}(\Omega)$,

$$
\begin{equation*}
\int_{\Omega}\left|D u^{+}\right|^{2} \mathrm{~d} x \geqslant \lambda_{1} \int_{\Omega}\left(u^{+}\right)^{2} \mathrm{~d} x . \tag{3.53}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
\int_{\Omega}\left[\left(u^{+}\right)^{p}-\lambda_{1}\left(u^{+}\right)^{2}\right] \mathrm{d} x \geqslant 0 \tag{3.54}
\end{equation*}
$$

which is impossible if $u^{+} \not \equiv 0$ and $\sup _{\Omega} u^{+}<\lambda_{1}^{1 /(p-2)}$ because $\left(u^{+}(x)\right)^{p}-\lambda_{1}\left(u^{+}(x)\right)^{2}<0$ for all $x \in \Omega$ such that $0<u(x)<\lambda_{1}^{1 /(p-2)}$.

A similar argument holds for $u^{-}$.

Proposition 3.9. Let $\left(\varepsilon_{i}\right)_{i}$ be a sequence of positive numbers and $\left(u_{i}\right)_{i}$ a sequence of functions in $H_{S}\left(\Omega_{\varepsilon_{i}}\right)$ such that $f_{\varepsilon_{i}}^{\prime}\left(u_{i}\right)=0 \forall i \in \mathbb{N}$ and $\lim _{i \rightarrow \infty} f_{\varepsilon_{i}}\left(u_{i}\right)=0$.

Then, if $u_{i}^{+} \not \equiv 0 \forall i \in \mathbb{N}$,
(a) $\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i}} \cap \chi_{\rho}}\left(u_{i}^{+}\right)^{q} \mathrm{~d} x=+\infty \forall q>\frac{n}{2}(p-1), \forall \rho>0$,
(b) $\lim _{i \rightarrow \infty} \sup \left\{u_{i}^{+}(x): x \in \Omega_{\varepsilon_{i}} \cap \chi_{\rho}\right\}=+\infty \forall \rho>0$.

Similar properties hold if $u_{i}^{-} \not \equiv 0 \forall i \in \mathbb{N}$.
Proof. Arguing by contradiction, assume that there exists $\bar{q}>\frac{n}{2}(p-1)$ and $\bar{\rho}>0$ such that, up to a subsequence,

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i}} \cap \chi_{\bar{\rho}}}\left(u_{i}^{+}\right)^{\bar{q}} \mathrm{~d} x<+\infty . \tag{3.55}
\end{equation*}
$$

Let us prove that, as a consequence,

$$
\begin{equation*}
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i}}}\left(u_{i}^{+}\right)^{q} \mathrm{~d} x=0 \quad \forall q<\bar{q} . \tag{3.56}
\end{equation*}
$$

In fact, for all $\rho>0$, we have

$$
\begin{equation*}
\int_{\Omega_{\varepsilon_{i}}}\left(u_{i}^{+}\right)^{q} \mathrm{~d} x \leqslant\left(\int_{\Omega_{\varepsilon_{i}} \cap \chi_{\rho}}\left(u_{i}^{+}\right)^{\bar{q}} \mathrm{~d} x\right)^{q / \bar{q}}\left(\text { meas } \chi_{\rho}\right)^{1-q / \bar{q}}+\int_{\Omega_{\varepsilon_{i} \backslash \chi_{\rho}}}\left(u_{i}^{+}\right)^{q} \mathrm{~d} x ; \tag{3.57}
\end{equation*}
$$

taking into account (c) of Lemma 3.3, it follows that

$$
\begin{equation*}
\left.\left.\limsup _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i}}}\left(u_{i}^{+}\right)^{q} \mathrm{~d} x \leqslant\left(\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon_{i}} \cap \chi_{\bar{\rho}}}\left(u_{i}^{+}\right)^{\bar{q}} \mathrm{~d} x\right)^{q / \bar{q}}\left(\text { meas } \chi_{\rho}\right)^{1-q / \bar{q}} \quad \forall \rho \in\right] 0, \bar{\rho}\right] . \tag{3.58}
\end{equation*}
$$

So, letting $\rho \rightarrow 0$ and taking into account (3.55), we get (3.56).
Now observe that, arguing as in the proof of property (c) of Lemma 3.3, one can prove that

$$
u_{i}(x) \leqslant \frac{1}{n(n-2) \omega_{n}} \int_{\Omega_{\varepsilon_{i}}} \frac{\left[u_{i}^{+}(y)\right]^{p-1}}{|x-y|^{n-2}} \mathrm{~d} y \quad \forall x \in \Omega_{\varepsilon_{i}}
$$

Then, for $q \in] \frac{n}{2}(p-1), \bar{q}[$, we obtain

$$
u_{i}(x) \leqslant c(p, q)\left(\int_{\Omega_{\varepsilon_{i}}}\left(u_{i}^{+}(y)\right)^{q} \mathrm{~d} y\right)^{(p-1) / q} \quad \forall x \in \Omega_{\varepsilon_{i}}
$$

for a suitable constant $c(p, q)$ (depending only on $p$ and $q$ ). Taking into account (3.56), it follows that $\lim _{i \rightarrow \infty} \sup _{\Omega_{\varepsilon_{i}}} u_{i}^{+}=0$, which contradicts Proposition 3.8 because we assumed $u_{i}^{+} \not \equiv 0 \forall i \in \mathbb{N}$. So, property (a) is proved.

Property (b) follows easily from (a), taking into account (c) of Lemma 3.3. In fact, if (b) does not hold, (c) of Lemma 3.3 (by the dominated convergence theorem) implies that, up to a subsequence,

$$
\lim _{i \rightarrow \infty} \int_{\Omega_{\varepsilon}}\left(u_{i}^{+}\right)^{q} \mathrm{~d} x=0 \quad \forall q>\frac{n}{2}(p-1),
$$

which contradicts (a).
Analogous arguments hold if we assume $u_{i}^{-} \not \equiv 0 \forall i \in \mathbb{N}$.

Proof of Theorem 2.1. For $\varepsilon>0$ small enough, let $\pm u_{1, \varepsilon}, \ldots, \pm u_{k, \varepsilon}$ be the critical points for $f_{\varepsilon}$ given by Proposition 3.7. Taking into account Corollary 3.4, these functions solve problem $P\left(\Omega_{\varepsilon}\right)$ for $\varepsilon>0$ small enough. Moreover, (a) follows from (a) of Lemma 3.3; (b) is equivalent to (a) because these functions belong to $M_{\varepsilon}$; (c) follows from (c) of Lemma 3.3; (d) and (e) are proved in Proposition 3.9.

Remark 3.10. The methods of critical points theory used in the proof of Proposition 3.7 give also information about the Morse index of the critical points $\pm u_{1, \varepsilon}, \ldots, \pm u_{k, \varepsilon}$ obtained for the functional $f_{\varepsilon}$ (which is not greater than $k$ ). Moreover, it is possible to estimate, in terms of the Morse index, the number of nodal regions of these functions (see, for example, $[2,3]$ ). Thus, in particular, we obtain that the solutions given by Theorem 2.1 do not have more than $k$ nodal regions.

Remark 3.11. The main step in the proof of Theorem 2.1 has been the fact that the critical points for the functional $f_{\varepsilon}$ (obtained in Proposition 3.7) correspond to critical values which tend to zero as $\varepsilon \rightarrow 0$. It is clear that this fact occurs because $p>\frac{2 n}{n-2}$, but it cannot hold for $p=\frac{2 n}{n-2}$. Therefore, these arguments cannot work in the critical case; indeed, for $p=\frac{2 n}{n-2}$, a solution having $k$ nodal regions corresponds to a critical value at least equal to $\frac{k}{n} S^{n / 2}$ (where $S$ is the best Sobolev constant).

However, using a different approach, also in the critical case it is possible to state similar multiplicity results and find solutions having analogous qualitative properties; in particular, one can find solutions which concentrate near the $x_{n}$-axis as $\varepsilon \rightarrow 0$, even if the corresponding critical values do not tend to zero (see [15]).
