On the largest prime factor of $n! + 2^n - 1$

par Florian LUCA et Igor E. SHPARLINSKI

RÉSUMÉ. Pour un entier $n \geq 2$, notons P(n) le plus grand facteur premier de n. Nous obtenons des majorations sur le nombre de solutions de congruences de la forme $n! + 2^n - 1 \equiv 0 \pmod{q}$ et nous utilisons ces bornes pour montrer que

$$\limsup_{n \to \infty} P(n! + 2^n - 1)/n \ge (2\pi^2 + 3)/18.$$

ABSTRACT. For an integer $n \geq 2$ we denote by P(n) the largest prime factor of n. We obtain several upper bounds on the number of solutions of congruences of the form $n! + 2^n - 1 \equiv 0 \pmod{q}$ and use these bounds to show that

$$\lim_{n \to \infty} \sup P(n! + 2^n - 1)/n \ge (2\pi^2 + 3)/18.$$

1. Introduction

For any positive integer k > 1 we denote by P(k) the largest prime factor of k and by $\omega(k)$ the number of distinct prime divisors of k. We also set P(1) = 1 and $\omega(1) = 0$.

It is trivial to see that P(n!+1) > n. Erdős and Stewart [4] have shown that

$$\limsup_{n \to \infty} \frac{P(n!+1)}{n} > 2.$$

This bound is improved in [7] where it is shown that the above upper limit is at least 5/2, and that it also holds for P(n! + f(n)) with a nonzero polynomial $f(X) \in \mathbb{Z}[X]$.

Here we use the method of [7], which we supplement with some new arguments, to show that

$$\limsup_{n \to \infty} \frac{P(n! + 2^n - 1)}{n} > (2\pi^2 + 3)/18.$$

We also estimate the total number of distinct primes which divide at least one value of $n! + 2^n - 1$ with $1 \le n \le x$.

Manuscrit reçu le 7 novembre 2003.

These results are based on several new elements, such as bounds for the number of solutions of congruences with $n! + 2^n - 1$, which could be of independent interest.

Certainly, there is nothing special in the sequence $2^n - 1$, and exactly the same results can be obtained for n! + u(n) with any nonzero binary recurrent sequence u(n).

Finally, we note that our approach can be used to estimate P(n! + u(n)) with an arbitrary linear recurrence sequence u(n) (leading to similar, albeit weaker, results) and with many other sequences (whose growth and the number of zeros modulo q are controllable).

Throughout this paper, we use the Vinogradov symbols \gg , \ll and \approx as well as the Landau symbols O and o with their regular meanings. For z > 0, $\log z$ denotes the natural logarithm of z.

2. Bounding the number of solutions of some equations and congruences

The following polynomial

$$(2.1) F_{k,m}(X) = (2^k - 1) \prod_{i=1}^m (X+i) - (2^m - 1) \prod_{i=1}^k (X+i) + 2^m - 2^k$$

plays an important role in our arguments.

Lemma 2.1. The equation

$$F_{k,m}(n) = 0$$

has no integer solutions (n, k, m) with $n \geq 3$ and $m > k \geq 1$.

Proof. One simply notices that for any $n \geq 3$ and $m > k \geq 1$

$$(2^{k} - 1) \prod_{i=1}^{m} (n+i) \ge 2^{k-1} (n+1)^{m-k} \prod_{i=1}^{k} (n+i)$$

$$\ge (n+1)2^{m-2} \prod_{i=1}^{k} (n+i) \ge 2^{m} \prod_{i=1}^{k} (n+i)$$

$$> (2^{m} - 1) \prod_{i=1}^{k} (n+i).$$

Hence, $F_{k,m}(n) > 0$ for $n \geq 3$.

Let $\ell(q)$ denote the multiplicative order of 2 modulo an odd integer $q \geq 3$. For integers $y \geq 0$, $x \geq y + 1$, and $q \geq 1$, we denote by $\mathcal{T}(y, x, q)$ the set of solutions of the following congruence

$$\mathcal{T}(y, x, q) = \{ n \mid n! + 2^n - 1 \equiv 0 \pmod{q}, \ y + 1 \le n \le x \},$$

and put T(y, x, q) = #T(y, x, q). We also define

$$T(x,q) = T(0,x,q)$$
 and $T(x,q) = T(0,x,q)$.

Lemma 2.2. For any prime p and integers x and y with $p > x \ge y+1 \ge 1$, we have

$$T(y, x, p) \ll \max\{(x - y)^{3/4}, (x - y)/\ell(p)\}.$$

Proof. We assume that $p \geq 3$, otherwise there is nothing to prove. Let $\ell(p) > z \geq 1$ be a parameter to be chosen later.

Let $y + 1 \le n_1 < \ldots < n_t \le x$ be the complete list of t = T(y, x, p) solutions to the congruence $n! + 2^n - 1 \equiv 0 \pmod{p}$, $y + 1 \le n \le x$. Then

$$\mathcal{T}(y, x, p) = \mathcal{U}_1 \cup \mathcal{U}_2,$$

where

$$U_1 = \{ n_i \in \mathcal{T}(y, x, p) \mid |n_i - n_{i+2}| \ge z, i = 1, \dots, t - 2 \},$$

and $U_2 = \mathcal{T}(y, x, p) \setminus \mathcal{U}_1$.

It is clear that $\#\mathcal{U}_1 \ll (x-y)/z$. Assume now that $n \in \mathcal{U}_2 \setminus \{n_{t-1}, n_t\}$. Then there exists a nonzero integers k and m with $0 < k < m \le z$, and such that

$$n! + 2^n - 1 \equiv (n+k)! + 2^{n+k} - 1 \equiv (n+m)! + 2^{n+m} - 1 \equiv 0 \pmod{p}.$$

Eliminating 2^n from the first and the second congruence, and then from the first and the third congruence, we obtain

$$\begin{split} n! \left(\prod_{i=1}^k (n+i) - 2^k \right) + 2^k - 1 \\ &\equiv n! \left(\prod_{i=1}^m (n+i) - 2^m \right) + 2^m - 1 \equiv 0 \pmod{p}. \end{split}$$

Now eliminating n!, we derive

$$(2^m - 1) \left(\prod_{i=1}^k (n+i) - 2^k \right) - (2^k - 1) \left(\prod_{i=1}^m (n+i) - 2^m \right) \equiv 0 \pmod{p},$$

or $F_{k,m}(n) \equiv 0 \pmod{p}$, where $F_{k,m}(X)$ is given by (2.1). Because $\ell(p) > z$, we see that for every $0 < k < m \le z$ the polynomial $F_{k,m}(X)$ has a nonzero coefficient modulo p and deg $F_{k,m} = m \le z$, thus for every 0 < k < m < z there are at most z suitable values of n (since $p > x \ge y + 1 \ge 1$).

Summing over all admissible values of k and m, we derive $\#\mathcal{U}_2 \ll z^3 + 1$. Therefore

$$T(y, x, p) \le \#\mathcal{U}_1 + \#\mathcal{U}_2 \ll (x - y)/z + z^3 + 1.$$

Taking $z = \min\{(x-y)^{1/4}, \ell(p) - 1\}$ we obtain the desired inequality. \square

Obviously, for any $n \ge p$ with $n! + 2^n - 1 \equiv 0 \pmod{p}$, we have $2^n \equiv 1 \pmod{p}$. Thus

$$(2.2) T(p, x, p) \ll x/\ell(p).$$

Lemma 2.3. For any integers $q \ge 2$ and $x \ge y + 1 \ge 1$, we have

$$T(y, x, q) \le \left(2 + O\left(\frac{1}{\log x}\right)\right) \frac{(x - y)\log x}{\log q} + O(1).$$

Proof. Assume that $T(y,x,q) \geq 6$, because otherwise there is nothing to prove. We can also assume that q is odd. Then, by the Dirichlet principle, there exist integers $n \geq 4$, $m > k \geq 1$, satisfying the inequalities

$$1 \le k < m \le 2 \frac{x - y}{T(y, x, q) - 4}, \qquad y + 1 \le n < n + k < n + m \le x,$$

and such that

$$n! + 2^n - 1 \equiv (n+k)! + 2^{n+k} - 1 \equiv (n+m)! + 2^{n+m} - 1 \equiv 0 \pmod{q}$$
.

Arguing as in the proof of Lemma 2.2, we derive $F_{m,k}(n) \equiv 0 \pmod{q}$. Because $F_{m,k}(n) \neq 0$ by Lemma 2.1, we obtain $|F_{m,k}(n)| \geq q$. Obviously, $|F_{m,k}(n)| = O(2^k x^m) = O((2x)^m)$. Therefore,

$$\log q \le m(\log x + O(1)) \le 2 \frac{(x - y)(\log x + O(1))}{T(y, x, p) - 4},$$

and the result follows.

Certainly, Lemma 2.2 is useful only if $\ell(p)$ is large enough.

Lemma 2.4. For any x the inequality $\ell(p) \ge x^{1/2}/\log x$ holds for all except maybe $O(x/(\log x)^3)$ primes $p \le x$.

Proof. Put $L = \lfloor x^{1/2} / \log x \rfloor$. If $\ell(p) \leq L$ then p|R, where

$$R = \prod_{i=1}^{L} (2^i - 1) \le 2^{L^2}.$$

The bound $\omega(R) \ll \log R/\log \log R \ll L^2/\log L$ concludes the proof. \square

We remark that stronger results are known, see [3, 6, 9], but they do not seem to be of help for our arguments.

3. Main Results

Theorem 3.1. The following bound holds:

$$\limsup_{n \to \infty} \frac{P(n! + 2^n - 1)}{n} \ge \frac{2\pi^2 + 3}{18} = 1.2632893\dots$$

Proof. Assuming that the statement of the above theorem is false, we see that there exist two constants $\lambda < (2\pi^2 + 3)/18$ and μ such that the inequality $P(n! + 2^n - 1) < \lambda n + \mu$ holds for all integer positive n.

We let x be a large positive integer and consider the product

$$W = \prod_{1 \le n \le x} (n! + 2^n - 1).$$

Let Q = P(W) so we have $Q \leq \lambda x + \mu$. Obviously,

(3.1)
$$\log W = \frac{1}{2}x^2 \log x + O(x^2).$$

For a prime p, we denote by s_p the largest power of p dividing at least one of the nonzero integers of the form $n! + 2^n - 1$ for $n \le x$. We also denote by r_p the p-adic order of W. Hence,

(3.2)
$$r_p = \sum_{1 \le s \le s_p} T(x, p^s),$$

and therefore, by (3.1) and (3.2), we deduce

(3.3)
$$\sum_{\substack{p|W\\p\leq Q}} \log p \sum_{1\leq s\leq s_p} T(x, p^s) = \log W = \frac{1}{2}x^2 \log x + O(x^2).$$

We let \mathcal{M} be the set of all possible pairs (p, s) which occur on the left hand side of (3.3), that is,

$$\mathcal{M} = \{(p,s) \mid p|W, \ p \le Q, \ 1 \le s \le s_p\},\$$

and so (3.3) can be written as

(3.4)
$$\sum_{(p,s)\in\mathcal{M}} T(x,p^s) \log p = \frac{1}{2}x^2 \log x + O(x^2).$$

As usual, we use $\pi(y)$ to denote the number of primes $p \leq y$, and recall that by the Prime Number Theorem we have $\pi(y) = (1 + o(1))y/\log y$.

Now we introduce subsets $\mathcal{E}_1, \mathcal{E}_2, \mathcal{E}_3, \mathcal{E}_4 \in \mathcal{M}$, which possibly overlap, and whose contribution to the sums on the left hand side of (3.4) is $o(x^2 \log x)$. After this, we study the contribution of the remaining set \mathcal{L} .

• Let \mathcal{E}_1 be the set of pairs $(p, s) \in \mathcal{M}$ with $p \leq x/\log x$. By Lemma 2.3, we have

$$\sum_{(p,s)\in\mathcal{E}_1} T(x,p^s) \log p \ll x \log x \sum_{(p,s)\in\mathcal{E}_1} \frac{1}{s} + \sum_{(p,s)\in\mathcal{E}_1} \log p$$

$$\ll x \log x \sum_{p\leq x/\log x} \log(s_p + 1)$$

$$+ \sum_{p\leq x/\log x} s_p \log p \ll x^2,$$

because obviously $s_p \ll x \log x$.

• Let \mathcal{E}_2 be the set of pairs $(p,s) \in \mathcal{M}$ with $s \geq x/(\log x)^2$. Again by Lemma 2.3, and by the inequality

$$s_p \ll x \frac{\log x}{\log p},$$

we have

$$\sum_{(p,s)\in\mathcal{E}_2} T(x,p^s) \log p \ll x \log x \sum_{(p,s)\in\mathcal{E}_2} \frac{1}{s} + \sum_{(p,s)\in\mathcal{E}_2} \log p$$

$$\ll x \log x \sum_{p\leq Q} \sum_{x/(\log x)^2 \leq s \leq s_p} \frac{1}{s} + \sum_{p\leq Q} s_p \log p$$

$$\ll x\pi(Q) \log x \log \log x \ll x^2 \log \log x,$$

because Q = O(x) by our assumption.

• Let \mathcal{E}_3 be the set of pairs $(p,s) \in \mathcal{M}$ with $\ell(p) \leq x^{1/2}/\log x$. Again by Lemmas 2.3 and 2.4, and by the inequality $s_p \ll x \log x$, we have

$$\sum_{(p,s)\in\mathcal{E}_3} T(x,p^s) \log p \ll x \log x \sum_{(p,s)\in\mathcal{E}_2} \frac{1}{s} + \sum_{(p,s)\in\mathcal{E}_3} \log p$$

$$\ll x \log x \sum_{\substack{p\leq Q\\\ell(p)\leq x^{1/2}/\log x}} \sum_{1\leq s\leq s_p} \frac{1}{s}$$

$$+ \sum_{\substack{p\leq Q\\\ell(p)\leq x^{1/2}/\log x}} s_p \log p$$

$$\ll x (\log x)^2 \sum_{\substack{p\leq Q\\\ell(p)\leq x^{1/2}/\log x}} 1 \ll x^2/\log x.$$

• Let \mathcal{E}_4 be the set of pairs $(p, s) \in \mathcal{M} \setminus (\mathcal{E}_1 \cup \mathcal{E}_3)$ with $s < x^{1/4}$. By Lemma 2.2 and by (2.2), we have

$$\sum_{(p,s)\in\mathcal{E}_3} T(x,p^s) \log p \ll x^{1/4} \sum_{p\leq Q} T(x,p) \log p$$

$$\ll x^{1/4} \sum_{p\leq Q} \left(p^{3/4} + x/\ell(p) \right) \log p$$

$$\ll x^{1/4} Q^{3/4} \sum_{p\leq Q} \log p$$

$$\ll x^{1/4} Q^{7/4} \ll x^2.$$

We now put $\mathcal{L} = \mathcal{M} \setminus (\mathcal{E}_1 \cup \mathcal{E}_2 \cup \mathcal{E}_3 \cup \mathcal{E}_4)$. The above estimates, together with (3.4), show that

(3.5)
$$\sum_{(p,s)\in\mathcal{L}} T(x,p^s) \log p = \frac{1}{2} x^2 \log x + O(x^2 \log \log x).$$

The properties of the pairs $(p, s) \in \mathcal{L}$ can be summarized as

$$p > \frac{x}{\log x}, \qquad \ell(p) \ge \frac{x^{1/2}}{\log x}, \qquad \frac{x}{(\log x)^2} \ge s \ge x^{1/4}.$$

In what follows, we repeatedly use the above bounds.

We now remark that because by our assumption $P(n!+2^n-1) \leq \lambda n + \mu$ for $n \leq x$, we see that $T(x,p^s) = T(\lfloor (p-\mu)/\lambda \rfloor, x, p^s)$.

Thus, putting $x_p = \min\{x, p\}$, we obtain

$$T(x,p^s) = T(\lfloor (p-\mu)/\lambda \rfloor, x, p^s) = T(\lfloor (p-\mu)/\lambda \rfloor, x_p, p^s) + T(x_p, x, p^s).$$

Therefore,

(3.6)
$$\sum_{(p,s)\in\mathcal{L}} T(x,p^s) \log p = U + V,$$

where

$$U = \sum_{(p,s)\in\mathcal{L}} T(\lfloor (p-\mu)/\lambda \rfloor, x_p, p^s) \log p,$$

and

$$V = \sum_{(p,s)\in\mathcal{L}} T(x_p, x, p^s) \log p.$$

To estimate U, we observe that, by Lemma 2.3,

$$U \le (2 + o(1)) \log x \sum_{p \le Q} \left(\left(x_p - \frac{p - \mu}{\lambda} \right) \sum_{x/\log x > s \ge x^{1/4}} \frac{1}{s} + O(1) \right)$$

$$\le (3/2 + o(1)) (\log x)^2 \sum_{p < Q} \left(x_p - \frac{p - \mu}{\lambda} \right) + O(x^2).$$

Furthermore,

$$\begin{split} \sum_{p \leq Q} \left(x_p - \frac{p - \mu}{\lambda} \right) &= \sum_{p \leq x} \left(p - \frac{p - \mu}{\lambda} \right) + \sum_{x$$

Hence

$$(3.7) U \le \left(\frac{3(\lambda - 1)}{4} + o(1)\right) x^2 \log x.$$

We now estimate V. For an integer $\alpha \geq 1$ we let \mathcal{P}_{α} be the set of primes $p \leq Q$ with

$$\ell(p) = \ldots = \ell(p^{\alpha}) \neq \ell(p^{\alpha+1}).$$

Thus, $\ell(p^{\alpha+1}) = \ell(p)p$.

Accordingly, let \mathcal{L}_{α} be the subset of pairs $(p, s) \in \mathcal{L}$ for which $p \in \mathcal{P}_{\alpha}$. We see that if $(p, s) \in \mathcal{L}$ and $n \leq x$, then $p^2 > n$, and therefore the *p*-adic order of n! is

$$\operatorname{ord}_p n! = \left| \frac{n}{p} \right|.$$

For $p \in \mathcal{P}_{\alpha}$ we also have

$$\operatorname{ord}_n(2^{\ell(p)} - 1) = \alpha.$$

Clearly, if $n \geq p$ then $\operatorname{ord}_p(n! + 2^n - 1) > 0$ only for $n \equiv 0 \pmod{\ell(p)}$. Because $\ell(p^{\alpha+1}) = p\ell(p) \gg x^{3/2}/(\log x)^2 > x$, we see that, for $p \leq n \leq x$,

$$\operatorname{ord}_p(2^n - 1) = \begin{cases} 0, & \text{if } n \not\equiv 0 \pmod{\ell(p)}, \\ \alpha, & \text{if } n \equiv 0 \pmod{\ell(p)}. \end{cases}$$

Therefore, for $n \leq \alpha p - 1$ and $n \equiv 0 \pmod{\ell(p)}$, we have

$$\operatorname{ord}_p(n! + 2^n - 1) \le \operatorname{ord}_p n! < n/(p - 1) \ll \log x.$$

Thus, $T(x_p, \alpha p - 1, p^s) = 0$ for $(p, s) \in \mathcal{L}_{\alpha}$.

On the other hand, for $n \ge (\alpha + 1)p$, we have $\operatorname{ord}_p(n!) > n/p - 1 \ge \alpha$. Hence, for $n \equiv 0 \pmod{\ell(p)}$, we derive

$$\operatorname{ord}_{p}(n! + 2^{n} - 1) = \operatorname{ord}_{p}(2^{n} - 1) = \alpha < n/p \ll \log x.$$

As we have mentioned $\operatorname{ord}_p(n!+2^n-1)=0$ for every $n\geq p$ with $n\equiv 0\pmod{\ell(p)}$. Thus, $T((\alpha+1)p,x,p^s)=0$ for $(p,s)\in\mathcal{L}_{\alpha}$.

For $\alpha = 1, 2, ...,$ let us define

$$Y_{\alpha,p} = \min\{x, \alpha p - 1\}$$
 and $X_{\alpha,p} = \min\{x, (\alpha + 1)p\}.$

We then have

$$V = \sum_{\alpha=1}^{\infty} V_{\alpha},$$

where

$$V_{\alpha} = \sum_{(p,s)\in\mathcal{L}_{\alpha}} T(x_p, x, p^s) \log p.$$

For every $\alpha \geq 1$, and $(p, s) \in \mathcal{L}_{\alpha}$, as we have seen,

$$T(x_p, x, p^s) = T(Y_{\alpha, p}, X_{\alpha, p}, p^s).$$

We now need the bound,

(3.8)
$$T(Y_{\alpha,p}, X_{\alpha,p}, p^s) \le \frac{X_{\alpha,p} - Y_{\alpha,p}}{\ell(p)} + 1,$$

which is a modified version of (2.2). Indeed, if $Y_{\alpha,p} = x$ then $X_{\alpha,p} = x$ and we count solutions in an empty interval. If $Y_{\alpha,p} = \alpha p - 1$ (the other alternative), we then replace the congruence modulo p^s by the congruence modulo p and remark that because $n > Y_{\alpha,p} \ge p$ we have $n! + 2^n - 1 \equiv 2^n - 1 \pmod{p}$ and (3.8) is now immediate.

We use (3.8) for $x^{1/2}/(\log x)^2 \ge s \ge x^{1/4}$, and Lemma 2.3 for $x/(\log x)^2 > s \ge x^{1/2}/(\log x)^2$. Simple calculations lead to the bound

$$V_{\alpha} \le (1 + o(1)) (\log x)^2 \sum_{p \in \mathcal{P}_{\alpha}} (X_{\alpha,p} - Y_{\alpha,p}) + O(x^2).$$

We now have

$$\sum_{p \in \mathcal{P}_{\alpha}} (X_{\alpha,p} - Y_{\alpha,p}) = \sum_{\substack{p \in P_{\alpha} \\ p \leq x/(\alpha+1)}} (p+1) + \sum_{\substack{p \in P_{\alpha} \\ x/(\alpha+1)$$

Thus, putting everything together, and taking into account that the sets \mathcal{P}_{α} , $\alpha = 1, 2, \ldots$, are disjoint, we derive

$$\begin{split} V &\leq (1+o(1)) \, (\log x)^2 \left(\sum_{p \leq x/2} p + \sum_{\alpha=1}^{\infty} \sum_{x/(\alpha+1)$$

Hence

(3.9)
$$V \le \left(\frac{27 - 2\pi^2}{24} + o(1)\right) x^2 \log x.$$

Substituting (3.7) and (3.9) in (3.6), and using (3.5), we derive

$$\frac{3(\lambda - 1)}{4} + \frac{27 - 2\pi^2}{24} \ge \frac{1}{2},$$

which contradicts the assumption $\lambda < (2\pi^2 + 3)/18$, and thus finishes the proof.

Theorem 3.2. For any sufficiently large x, we have:

$$\omega \left(\prod_{1 \le n \le x} (n! + 2^n - 1) \right) \gg \frac{x}{\log x}.$$

Proof. In the notation of the proof of Theorem 3.1, we derive from (3.2) and Lemma 2.3, that

$$r_p \ll \sum_{1 \leq s \leq s_p} \frac{x \log x}{s \log p} + 1 \ll \frac{x \log x \log(s_p + 1)}{\log p} + s_p.$$

Obviously $s_p \ll x \log x / \log p$, therefore $r_p \ll x (\log x)^2 / \log p$. Thus, for any prime number p,

$$p^{r_p} = \exp\left(O\left(x(\log x)^2\right)\right),\,$$

П

which together with (3.1) finishes the proof.

4. Remarks

We recall the result of Fourry [5], which asserts that $P(p-1) \ge p^{0.668}$ holds for a set of primes p of positive relative density (see also [1, 2] for this and several more related results). By Lemma 2.4, this immediately implies that $\ell(p) \ge p^{0.668}$ for a set of primes p of positive relative density. Using this fact in our arguments, one can easily derive that actually

$$\limsup_{n \to \infty} \frac{P(n! + 2^n - 1)}{n} > \frac{2\pi^2 + 3}{18}.$$

However, the results of [5], or other similar results like the ones from [1, 2], do not give any effective bound on the relative density of the set of primes with $P(p-1) \ge p^{0.668}$, and thus cannot be used to get an explicit numerical improvement of Theorem 3.1.

We also remark that, as in [7], one can use lower bounds on linear forms in p-adic logarithms to obtain an "individual" lower bound on $P(n!+2^n-1)$. The ABC-conjecture can also used in the same way as in [8] for P(n!+1).
