CALCUL APPROCHE DE LA SERIE D'IWASAWA
POUR LES CORPS QUADRATIQUES ($p = 3$)

Shinju KOBAYASHI

CALCUL APPROCHE DE LA SERIE D' IWASAWA

POUR LES CORPS QUADRATIQUES ($p = 3$)

par Shinju KOBAYASHI

1. Soit p un nombre premier et χ un caractère de Dirichlet pair. Nous supposons p impair puisqu'il s'agira d'un calcul pour $p=3$. On sait que la fonction L p -adique $L_p(s, \chi)$ a une représentation par une série formelle. Pour expliciter cette représentation, soit χ de conducteur dp^j avec $p \nmid d$, $j \geq 0$ et soit $\chi = \theta \psi$ sa décomposition en facteur de genre 1 et de genre 2 : θ est de conducteur divisant dp et ψ est de conducteur p^j et d'ordre p^{j-1} (ψ est non-trivial seulement si $j \geq 2$). Alors il existe un élément $f(T; \theta)$ du corps quotient de $\Lambda = \mathfrak{D}_\theta[[T]]$ ($\mathfrak{D}_\theta =$ l'anneau des entiers du corps K_θ engendré par les valeurs de θ sur \mathbb{Q}_p tel que :

$$L_p(s, \chi) = f(\psi(1+q_0)^{-1} (1+q_0)^s - 1; \theta), \quad q_0 = dp.$$

2. Iwasawa a donné $f(T; \theta)$ comme la limite projective de l'image par $\theta^{-1} \omega$ ($\omega =$ le caractère de Teichmüller) des éléments de Stickelberger.

Soient $q_n = dp^{n+1}$, $K_n = \mathbb{Q}(\zeta_{q_n})$, $\Gamma_n = G(K_n/K_0)$, $G(K_n/\mathbb{Q}) = \Delta \times \Gamma_n$ la décomposition de $G(K_n/\mathbb{Q})$ telle que $\Delta \cong G(K_0/\mathbb{Q})$, et enfin $\delta : \mathbb{Z} \rightarrow \Delta$ et $\gamma_n : \mathbb{Z} \rightarrow \Gamma_n$ les applications d'Artin. θ et ω sont donc des caractères de Δ et ψ est un caractère de Γ_n ($n+1 \geq j$).

On définit alors :

$$\xi_n = -\frac{1}{q_n} \sum_{\substack{0 < a < q_n \\ (a, q_0) = 1}} a \delta(a)^{-1} \gamma_n(a)^{-1} \in \mathbb{Q}_p[\Delta \times \Gamma_n],$$

et on prend son image par $\theta^{-1} \omega$:

$$\xi_n(\theta) = \theta^{-1} \omega(\xi_n) = -\frac{1}{q_n} \sum_a a \theta \omega^{-1}(a) \gamma_n(a)^{-1} \in K_\theta[\Gamma_n].$$

Dans le cas $\theta \neq 1$, on a $\xi_n(\theta) \in \mathfrak{D}_\theta[\Gamma_n]$ et la famille $\{\xi_n(\theta)\}$ a une limite dans $\varprojlim \mathfrak{D}_\theta[\Gamma_n]$ (définie par la projection $\Gamma_m \rightarrow \Gamma_n$ pour $m \geq n$). Alors $f(T; \theta)$ est la série qui correspond à $\lim \xi_n(\theta)$ dans l'isomorphisme $\varprojlim \mathfrak{D}_\theta[\Gamma_n] \longrightarrow \Lambda$ défini par $\lim \gamma_n(1+q_0) \longmapsto 1+T$. A noter que Γ_n est un groupe cyclique d'ordre p^n engendré par $\gamma_n(1+q_0)$.

On a en particulier :

$$f(T; \theta) \equiv - \sum_{i=1}^{p^n} \left(\frac{1}{q_n} \sum_{\gamma_n(a) = \gamma_n(1+q_0)^i} a \theta \omega^{-1}(a) \right) (1+T)^{p^n-i} \pmod{(1+T)^{p^n} - 1}.$$

Pour plus de détails, voir L. Washington, Introduction to cyclotomic fields, Springer-Verlag.

3. Degré d'approximation. Dans le développement

$$(1+T)^{p^n} - 1 = \sum_{i=1}^{p^n-1} \binom{p^n}{p_i} T^i + T^{p^n}, \text{ on a (v étant la valuation p-}$$

adique) :

$$\begin{aligned} v \left[\binom{p^n}{p_i} \right] &= v \left[p^n (p^n - 1) \dots (p^n - i + 1) / i! \right] \\ &= v \left[p^n \cdot 1 \dots (i-1) / i! \right] \\ &= n - v(i). \end{aligned}$$

Par conséquent, si $f(T) = \sum a_k T^k$ et $g(T) = \sum b_k T^k$ sont deux éléments de Λ et si $f \equiv g \pmod{(1+T)^{p^n} - 1}$, on a, pour $k < p^n$,

$$a_k \equiv b_k \pmod{p^\alpha}, \quad \alpha = \min_{1 \leq i \leq k} (n - v(i)).$$

Donc le calcul au niveau q_n ne donne pas tous les coefficients de $f(T; \theta)$ modulo p^n . Toutefois, on a toujours $\alpha > 0$.

4. Le calcul effectué. C'est le cas des caractères quadratiques réels $\chi = \theta$ et $p = 3$, donc $\mathfrak{D}_\theta = \mathbb{Z}_3$ et $\Lambda = \mathbb{Z}_3[[T]]$. Dans ce

cas , la série est à rapprocher plutôt du corps imaginaire correspondant au caractère miroir $\theta \omega$: le terme constant est égal à $(1 - \theta \omega(3))$ fois le nombre de classes du corps imaginaire , le degré de Weierstrass de la série est égal à l'invariant d'Iwasawa λ de ce corps , ... etc . C'est pourquoi nous avons paramétrisé la table par $\mathbb{Q}(\sqrt{-m})$ correspondant au $\theta \omega$.

Nous avons envisagé principalement de déterminer le polygone de Newton du polynôme distingué associé à $f(T; \theta)$ et donc nous n'avons pas poussé l'approximation plus loin . Rappelons que le polygone de Newton d'un polynôme $\sum_{k=0}^m a_k T^k \in \mathbb{Z}_p[T]$ est l'enveloppe d'en bas des points $(k, v(a_k))$, $k = 0, \dots, m$. Il donne la valuation des racines du polynôme de la manière suivante :

si il y a un côté de coefficient d'inclinaison $-\alpha$ et de longueur (horizontale) m_1 , le polynôme possède m_1 racines de valuation p -adique α . A noter que si $f(T; \theta) = uP$, où P est un polynôme distingué et $u \in \Lambda^\times$, les polygones pour $f(T; \theta)$ et P coïncident dans l'intervalle $[0, \deg P]$.

Tous les calculs ont été faits sur le mini-ordinateur OKITAC - 4300 C de notre laboratoire à Chiba .

5. Table 1 (p. 1 ~ 59) . C'est le résultat du calcul au niveau q_2 pour les $m < 10000$ pour lesquels le terme constant de la série $\equiv 0 \pmod{3}$. A ce niveau-là , on ne peut obtenir d'information que sur les coefficients a_0, \dots, a_8 de $f(T; \theta)$. C'est un hasard si l'on a $\lambda =$ degré de Weierstrass ≤ 8 pour tous les cas étudiés .

Les chiffres sont , de gauche à droite :

m , la décomposition en composantes primaires de q_2 (quand $m \not\equiv 0 \pmod{3}$) , nous avons mis 27 à la fin) et les valeurs approchées de

$-a_0, \dots, -a_8$ (i.e. les coefficients de $-f(T; \theta)$). Parmi ces coefficients on a $a_0 = (1 - \theta\omega(3)) \times h(\mathbb{Q}(\sqrt{-m}))$. Lorsque $1 - \theta\omega \neq 0$, i.e. $m \not\equiv 2 \pmod{3}$, nous avons noté $q \sim, 3.3 \sim, \dots$ etc. à côté de $-a_0$ suivant que le 3-groupe des classes est isomorphe à $\mathbb{Z}/q\mathbb{Z}$, $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$, \dots etc.

Comme nous avons remarqué plus haut, le calcul au niveau q_n donne a_0, a_1 et a_2 modulo 3^n et a_3, \dots, a_8 modulo 3^{n-1} . Par exemple, pour $m = 41$, on a -2 ($-a_3$ au niveau q_2) $\not\equiv 19$ ($-a_3$ au niveau q_4) $\pmod{3^2}$ (voir Table 2). Pour la plupart des cas, Table 1 suffit pour déterminer le polygone de Newton, même s'il reste encore des coefficients marqués 0. C'est ainsi qu'on voit que le polynôme distingué associé est irréductible si $v(a_0) = 1$, qu'il est T- (polynôme irréductible) si $m \equiv 2 \pmod{3}$ et $v(a_1) = 1$, que le polygone est :

pour $m = 8746$ (\hat{x} signifiant que le point $(i, v(a_i))$ est au moins à la hauteur de la marque x), \dots etc.

6. Table 2 (p. 60 ~ 64). Elle complète Table 1 pour 280 cas indéterminés, en donnant le résultat du calcul juste suffisamment approfondi pour déterminer le polygone correspondant.

Les chiffres sont, de gauche à droite : m, n indiquant le niveau avec 3^n et les valeurs approchées de $-a_0, \dots, -a_8$.
