#### REPRESENTATIONS OF SEMI DIRECT PRODUCTS OF GROUPS

by

#### S. Sankaran

#### Introduction

Let  $G_1$  be a locally compact Abelian group,  $G_2$  a locally compact group of continuous automorphisms of  $G_1$ . In this paper we characterise all pairs of unitary representations  $\rho$  and  $\sigma$  of  $G_1$  and  $G_2$  respectively in a Hilbert space  $\mathfrak{H}$ , where  $\rho$  is cyclic and

$$\sigma(\alpha)\rho(x)\sigma(\alpha^{-1}) = \rho(\alpha[x]), \ \alpha \in G_2, x \in G_1.$$
 (\*)

A set of necessary and sufficient conditions for a pair  $(\rho_1, \sigma_1)$  to be unitarily equivalent to a pair  $(\rho_2, \sigma_2)$  is given.

It can be shown that the commutation relations (\*) define a system of imprimitivity for the representation  $\sigma$ . In [[3] § 14.] Mackey investigates these representations, from a different point of view from ours, primarily as an application of his theory of induced representations.

I would like to thank the referee for his helpful comments.

#### 1. Preliminaries

DEFINITION 1.1. Let G be a locally compact group. A unitary representation of G is a homomorphism  $\Pi:g\to\Pi(g)$  of G into the group of unitary transformations of a Hilbert space  $\mathfrak{H}(\Pi)$ , such that  $\Pi$  is continuous in the weak topology for operators. A closed linear manifold  $\mathfrak{M}$  is called an invariant subspace for  $\Pi$  if  $\Pi(g) \xi \in \mathfrak{M}$  for all  $g \in G$  and all  $\xi \in \mathfrak{M}$ . An invariant subspace  $\mathfrak{M}$  is said to be a cyclic subspace for  $\Pi$  if there is an element  $\xi_0$  in  $\mathfrak{H}(\Pi)$ , such that the smallest invariant subspace for  $\Pi$  containing  $\xi_0$  is  $\mathfrak{M}$ .  $\xi_0$  is called a relative cyclic vector for  $\Pi$ . If  $\mathfrak{H}(\Pi)$  is a cyclic subspace, then  $\Pi$  is said to be cyclic. The intertwining algebra of a representation  $\Pi$  is the set

$$R(\Pi, \Pi) = \{T : T\Pi(g) = \Pi(g)T, g \in G\},\$$

T being bounded, everywhere defined, linear transformations on  $\mathfrak{H}(\Pi)$ .

DEFINITION 1.2. Let  $\mathfrak{H}$  be a Hilbert space.  $A^{-*}$  algebra  $\mathfrak{A}$  of (bounded,

everywhere defined, linear) transformations of  $\mathfrak{H}$  is called a von Neumann algebra, if  $\mathfrak{A}$  is closed in the weak topology for operators. A closed linear manifold  $\mathfrak{M}$  is called an invariant subspace for  $\mathfrak{A}$ , if  $A\xi \in \mathfrak{M}$  for all  $A \in \mathfrak{A}$  and all  $\xi \in \mathfrak{M}$ . An invariant subspace  $\mathfrak{M}$  is said to be a cyclic subspace for  $\mathfrak{A}$  if there is an element  $\xi_0$  in  $\mathfrak{H}$ , such that the smallest invariant subspace for  $\mathfrak{A}$  containing  $\xi_0$  is  $\mathfrak{M}$ . If  $\mathfrak{H}$  is an invariant subspace for  $\mathfrak{A}$ , then  $\mathfrak{A}$  is said to be cyclic. The commutant of  $\mathfrak{A}$  is the set

$$\mathfrak{A}' = \{T : TA = AT, A \in \mathfrak{A}\},\$$

T being bounded, everywhere defined, linear transformations on  $\mathfrak{H}$ .

It is easy to prove that a closed linear manifold  $\mathfrak{M} \subseteq \mathfrak{H}(\Pi)$  (resp.  $\mathfrak{M} \subseteq \mathfrak{H}$ ) is a cyclic subspace for  $\Pi$  (resp.  $\mathfrak{A}$ ) if and only if there is an element  $\xi_0 \in \mathfrak{H}(\Pi)$  (resp.  $\xi_0 \in \mathfrak{H}$ ) such that the closed linear manifold generated by  $(\Pi(g)\xi_0:g\in G)$  (resp.  $(A\xi_0:A\in \mathfrak{A})$ ) is  $\mathfrak{M}$ .

If S is a set of elements in a Hilbert space the closed linear manifold generated by S is denoted by  $[s:s\in S]$ .

Let  $\Pi: g \to \Pi(g)$  be a representation of a locally compact group G. We shall often use the following well-known results

#### LEMMA 1.1.

- (i)  $R(\Pi, \Pi)$  is a von Neumann algebra;
- (ii)  $R(\Pi, \Pi)'$  is the smallest von Neumann algebra containing the operators  $(\Pi(g): g \in G)$ ;
- (iii)  $\mathfrak{M}$  is an invariant subspace for  $\Pi$  (resp.  $R(\Pi, \Pi)'$ ) if and only if P, the projection whose range is  $\mathfrak{M}$ , belongs to  $R(\Pi, \Pi)$ .
- (iv) A closed linear manifold  $\mathfrak{M}$  is a cyclic subspace for  $\Pi$  if and only if  $\mathfrak{M}$  is a cyclic subspace for  $R(\Pi, \Pi)'$ .

DEFINITION 1.3. Let X be a locally compact space,  $\mu$  a finite regular measure defined on the  $\sigma$ -ring of Borel subsets of X. We denote by L(X) the set of all continuous functions with compact support; C(X) the set of all continuous functions on X. If  $f \in L(X)$  we denote by  $M_f$  the operator on  $L^2(X, \mu)$  defined by  $(M_f h)(x) = f(x)h(x)$ , where  $h \in L^2(x, \mu)$ .

Lemma 1.2. Let  $G_1$  be a locally compact Abelian group,  $\hat{G}_1$  the character group of  $G_1$  and  $\mu$  a finite regular measure defined on the  $\sigma$ -ring of Borel subsets of  $\hat{G}_1$ . The mapping  $M: x \to M_x$ , where  $(M_x f)(\tau) = x(\tau)f(\tau)$ ,  $f \in L^2(\hat{G}_1, \mu)$ ,  $x \in G_1$  is a cyclic representation of  $G_1$ .

PROOF. It is easy to verify that  $M: x \to M_x$  is a weakly continuous unitary representation of  $G_1$ . We shall show that M is cyclic.

Let e be the function on  $\hat{G}_1$ ,  $e(\tau) = 1$ . Since  $\mu$  is a finite measure on  $\hat{G}_1$ , e belongs to  $L^2(\hat{G}_1, \mu)$  and therefore  $x = M_x e \in L^2(\hat{G}_1, \mu)$  for all  $x \in G_1$ . Denote by F the set of all finite linear combination of elements

of  $G_1$ . We recall [[4] § 31, cor. 4] that every continuous function on  $\hat{G}_1$  can be approximated uniformly on compact sets by members of F. If f,  $h_1$ ,  $h_2$  are continuous functions with compact supports and  $\varepsilon > 0$ , we can find  $s \in F$  such that

$$|f(\tau)-s(\tau)| < \frac{\varepsilon}{||h_1|| \, ||h_2||}$$
 for all  $\tau \in k_1 \cap k_2$ 

where  $K_i$  is the support of  $h_i$ . Hence

$$\begin{aligned} |((M_f - M_s)h_1, h_2)| &= \left| \int_{G_1} (f(\tau) - s(\tau))h_1(\tau)\overline{h_2(\tau)} d\mu(\tau) \right| \\ &< \frac{\varepsilon}{||h_1|| \, ||h_2||} \, ||h_1|| \, ||h_2|| = \varepsilon. \end{aligned}$$

This is true for all  $h_1 \in L(\hat{G}_1)$  and  $h_2 \in L(\hat{G}_1)$ . Since  $L(\hat{G}_1)$  is dense in  $L^2(\hat{G}_1, \mu)$ , we have proved that  $(M_f: f \in L(\hat{G}_1))$  belongs to the weakly closed algebra generated by  $(M_x: x \in G_1)$ . From Lemma 1.1 (ii) we deduce that  $(M_f: f \in L(\hat{G}_1)) \subseteq R(\Pi, \Pi)'$  and therefore from the (iv) of Lemma 1.1. we deduce that  $f = M_f e \in [M_x e: x \in G_1]$ . That is  $L(\hat{G}_1) \subseteq [M_x e: x \in G_1]$ . We complete the proof by observing that  $L(\hat{G}_1)$  is dense in  $L^2(G_1, \mu)$ .

LEMMA 1.3. Let  $\Pi: x \to \Pi(x)$  be a cyclic representation of a locally compact Abelian group  $G_1$ . There is a regular finite measure  $\mu$  on  $\hat{G}_1$ , and a linear isometry  $S: \mathfrak{H}(\Pi) \to L^2(\hat{G}_1, \mu)$  such that  $S\Pi(x)S^{-1} = M_x$ , where  $M: x \to M_x$  is the representation of  $G_1$  defined in Lemma 1.2.

PROOF. Let  $\xi_0$  be a cyclic element for the cyclic representation  $\Pi$ , and let  $\Phi(x) = (\Pi(x)\xi_0, \xi_0)$ . There is a positive functional P on  $R(G_1)$ , the group algebra of  $G_1$ , which corresponds to the continuous positive definite function  $\Phi$ . Since  $R(G_1)$  is a commutative Banach algebra, the positive functional P can be represented in the form

$$P(f) = \int_{A} f(\tau) d\mu(\tau).$$

The spectrum  $\Delta$  of  $R(G_1)$  is homeomorphic to  $\hat{G}_1 \cup \{L^1(G_1)\}$  and  $\mu(\{L^1(G_1)\}) = 0$ . Therefore, the measure  $\mu$  may be considered as a measure defined on  $\hat{G}_1[[4] \S 31$ , sec. 3].

The Gelfand isomorphism theorem allows us to regard P as a positive functional on  $C(\Delta)$ , where  $C(\Delta)$  is the set of all continuous functions on  $\Delta$ . The positive functional P defines a representation of  $C(\Delta)$  which is equivalent to the representation  $M: f \to M_f$  on  $L^2(\Delta, \mu)$ , where

$$(M_f g)(\delta) = f(\delta)g(\delta), g \in L^2(\Delta, \mu).$$

[[4]. ch. 4. § 17]. Since  $G_1 \subseteq C(\Delta)$ , we obtain a representation  $M: x \to M_x$  of  $G_1$  in

$$L^2(\Delta,\mu)=L^2(\widehat{G}_1,\mu),$$

where

$$(M_x g)(\tau) = x(\tau)g(\tau).$$

Since the representations M and  $\Pi$  of  $G_1$  define the same representation of  $R(G_1)$ , namely the representation defined by the positive functional P, the representations M and  $\Pi$  are equivalent. [[4] § 29, sec. 3].

### 2. Semi-direct products

Let G be a locally compact group,  $G_2$  a locally compact group of automorphisms of G such that the mapping  $(g, \alpha) \to \alpha[g]$  of  $G \times G_2$  into G is continuous in both variables. The semi-direct product  $G \otimes G_2$  is the set of all pairs  $(g, \alpha)$ ,  $g \in G$ ,  $\alpha \in G_2$ , whose group operation is defined by

$$(g, \alpha)(h, \beta) = (g\alpha[h], \alpha\beta).$$

 $G \otimes G_2$  is a locally compact group in the product topology. The mapping  $g \to (g, \varepsilon)$  where  $\varepsilon$  is the identity of  $G_2$  is an isomorphism between G and a closed normal subgroup of  $G \otimes G_2$ . The mapping  $\alpha \to (e, \alpha)$  where e is the identity element of G is an isomorphism between  $G_2$  and a closed subgroup of  $G \otimes G_2$ . Finally,  $(g, \alpha) = (g, \varepsilon)(e, \alpha)$ . [[2] pp. 6-7, 58-59, [3] § 14]. The proof of the following lemma is routine.

LEMMA 2.1. Let  $\rho: g \to \rho(g)$  and  $\sigma: \alpha \to \sigma(\alpha)$  be representations of G and  $G_2$  respectively in a Hilbert space  $\mathfrak{H}$ . The mapping  $\Pi: (g, \alpha) \to \Pi(g, \alpha)$ , where  $\Pi(g, \alpha) = \rho(g)\sigma(\alpha)$  is a representation of  $G \otimes G_2$  if and only if

$$\sigma(\alpha)\rho(g)\sigma(\alpha^{-1}) = \rho(\alpha[g]).$$

In the following pages let  $G_1$  be a locally compact Abelian group,  $\hat{G}_1$  the character group of  $G_1$ ,  $G_2$  a locally compact group of continuous automorphisms of  $G_1$  such that the mapping  $(x, \alpha) \to \alpha[x]$  of  $G_1 \times G_2$  to  $G_1$  is continuous in both variables. The group  $G_2$  acts as a group of automorphisms of  $\hat{G}_1$ , if we define  $[\tau]\alpha$  by the equation  $([\tau]\alpha)(x) = \tau(\alpha[x]), x \in G_1$ . [[2] 26.9].

DEFINITION 2.1. Let  $\mu$  be a finite Borel measure defined on  $\hat{G}_1$ , and for each  $\alpha \in G_2$  let  $\mu_{\alpha}$  be the measure on  $\hat{G}_1$  defined by  $\mu_{\alpha}(B) = \mu([B]\alpha)$ . The measure  $\mu$  is said to be  $G_2$ -quasi invariant if  $\mu_{\alpha}$  is absolutely continuous with respect to  $\mu$  for all  $\alpha \in G_2$ .

Lemma 2.2. Let  $\mu$  be a  $G_2$ -quasi invariant measure on  $\hat{G}_1$ . The mapping

$$\Pi:(x,\alpha)\to\Pi(x,\alpha)=\Pi(x,\varepsilon)\Pi(e,\alpha),$$

where

$$(\Pi(x,\varepsilon)f)(\tau)=x(\tau)f(\tau)$$

and

$$(\Pi(e,\alpha)f)(\tau) = \sqrt{\frac{d\mu_{\alpha}}{d\mu}}(\tau)f([\tau]\alpha), f \in L^2(G_1,\mu)$$

is a representation of  $G_1 \otimes G_2$  in  $L^2(\hat{G}_1, \mu)$ .

As the proof consists of a routine verification of the condition given in lemma 2.1, we omit the proof.

THEOREM 2.1. Let  $\Pi:(x,\alpha)\to\Pi(x,\alpha)$  be a representation of  $G_1\otimes G_2$  in a Hilbert space  $\mathfrak{H}(\Pi)$  such that the representation  $\Pi(x,\epsilon)$  of  $G_1$  in  $\mathfrak{H}(\Pi)$  is cyclic. There is a  $G_2$ -quasi invariant measure  $\mu$  on  $\hat{G}_1$  and a linear isometry S from  $\mathfrak{H}(\Pi)$  on to  $L^2(\hat{G}_1,\mu)$  such that

$$S\Pi(x,\varepsilon)S^{-1}f(\tau) = x(\tau)f(\tau)$$

and

$$S\Pi(e,\alpha)S^{-1}f(\tau) = a(\tau,\alpha)\sqrt{\frac{d\mu_{\alpha}}{d\mu}}(\tau)f([\tau]\alpha)$$

where  $a(\tau, \alpha)$  is a Borel function on  $\hat{G}_1 \times G_2$  with the following properties:

i 
$$|a(\tau, \alpha)| = 1$$
 almost everywhere, and  
ii  $a(\tau, \alpha_1, \alpha_2) = a(\tau, \alpha_1) a([\tau]\alpha_1, \alpha_2)$ , a.e.

PROOF. Let  $\rho(x) = \Pi(x, \varepsilon)$  and  $\sigma(\alpha) = \Pi(e, \alpha)$ . Since  $\rho$  is a cyclic representation of  $G_1$  in  $\mathfrak{H}(\Pi)$ , it follows from Lemma 1.2 that there is a finite Borel measure  $\mu$  on  $\hat{G}_1$  and a linear isometry S from  $\mathfrak{H}(\Pi)$  onto  $L^2(\hat{G}_1, \mu)$  such that  $S\rho(x)S^{-1}f(\tau) = x(\tau)f(\tau)$ . The well-known Stone-Naimark-Ambrose-Godement theorem asserts that there is a projection valued measure  $P: B \to P_B$  on the Borel subsets of  $\hat{G}_1$  to the projections in the intertwining algebra  $R(\rho, \rho)'$  such that [[4] § 31. Th. 6]

$$(\rho(x)\xi,\eta) = \int_{\hat{G}_{\tau}} x(\tau)d(P_{\tau}\xi,\eta) \tag{1}$$

for every pair of elements  $\xi$  and  $\eta$  in  $\mathfrak{H}(\Pi)$ . Moreover, if  $\xi_0$  is a cyclic element for the representation  $\rho$  then the measure  $\mu$  is equivalent to the measure  $\nu$  where  $\nu(B) = ||P_B \xi_0||^2$ . Now

$$(\sigma(\alpha)\rho(x)\sigma(\alpha^{-1})\xi,\,\eta)=\rho(\alpha[x]\xi,\,\eta). \tag{2}$$

From (1) we have

$$(\sigma(\alpha)\rho(x)\sigma(\alpha^{-1})\xi, \eta) = (\rho(x)\sigma(\alpha^{-1})\xi, \sigma(\alpha^{-1})\eta)$$

$$= \int_{\hat{G}_1} x(\tau)d(P_{\tau}\sigma(\alpha^{-1})\xi, \sigma(\alpha^{-1})\eta)$$

$$= \int_{\hat{G}_1} x(\tau)d(\sigma(\alpha)P_{\tau}\sigma(\alpha^{-1})\xi, \eta)$$
(3)

Also,

$$(\rho(\alpha[x])\xi,\eta) = \int_{\hat{G}_1} \alpha[x](\tau)d(P_{\tau}\xi,\eta)$$

$$= \int_{\hat{G}_1} x([\tau]\alpha)d(P_{\tau}\xi,\eta) = \int_{\hat{G}_1} x(\tau)d(P_{[\tau]\alpha-1}\xi,\eta) \quad (4)$$

It follows from (2), (3) and (4) that

$$\sigma(\alpha)P_B\sigma(\alpha^{-1}) = P_{\lceil B\rceil\alpha^{-1}}. \tag{5}$$

Now  $\mu(B)=0$  implies  $\nu(B)=0$  and consequently  $P_B\xi_0=0$ . Since  $P_B\in R(\rho,\rho)$ , the equation  $0=TP_B\xi_0=P_BT\xi_0$ ,  $T\in R(\rho,\rho)'$  implies  $P_BE=0$  where E is the projection on the closed linear manifold generated by  $(T\xi_0:T\in R(\rho,\rho)')$ . However, E=I because  $\xi_0$  is a cyclic element for  $\rho$ . Therefore  $P_B=0$ . Thus  $\mu(B)=0$  implies  $P_B=0$ , and from (5) it follows that  $P_{[B]\alpha^{-1}}=0$ . That is,  $\mu(B)=0$  implies  $\nu([B]\alpha^{-1})=0$ . Since  $\mu$  and  $\nu$  are equivalent,  $\nu([B]\alpha^{-1})=0$ , implies  $\mu([B]\alpha^{-1})=0$ .

Hence  $\mu_{\alpha^{-1}}$  is absolutely continuous with respect to  $\mu$ . Since  $\alpha \in G_2$  is arbitrary, we have shown that  $\mu$  is  $G_2$  quasi invariant.

Let

$$\sigma_0(\alpha)f(\tau) = \sqrt[]{\frac{d\mu_\alpha}{d\mu}}(\tau)f([\tau]\alpha), \, f \in L^2(\hat{G}_1, \mu)$$

and

$$\sigma_1(\alpha) = S\sigma(\alpha)S^{-1}\sigma_0(\alpha^{-1})$$

where S is the linear isometry  $\mathfrak{H}(\Pi) \to L^2(\hat{G}_1, \mu)$  introduced in the first paragraph of this proof. It is clear that  $\sigma_1(\alpha)$  is a unitary transformation. Now, from the relation  $\sigma_0(\alpha^{-1})M_x = M_{\alpha^{-1}[x]}\sigma_0(\alpha^{-1})$ , we have

$$\begin{split} \sigma_{1}(\alpha)S\rho(x)S^{-1}(\tau) &= S\sigma(\alpha)S^{-1}\sigma_{0}(\alpha^{-1})M_{x}f(\tau) \\ &= S\sigma(\alpha)S^{-1}M_{\alpha^{-1}[x]}\sigma_{0}(\alpha^{-1})f(\tau) \\ &= S\sigma(\alpha)S^{-1}S\rho(\alpha^{-1}[x])S^{-1}\sigma_{0}(\alpha^{-1})f(\tau) \\ &= S\sigma(\alpha)\rho(\alpha^{-1}[x])S^{-1}\sigma_{0}(\alpha^{-1})f(\tau) \\ &= S\rho(\alpha\alpha^{-1}[x])\sigma(\alpha)S^{-1}\sigma_{0}(\alpha^{-1})f(\tau) \\ &= S\rho(x)\sigma(\alpha)S^{-1}\sigma_{0}(\alpha^{-1})f(\tau) \\ &= S\rho(x)S^{-1}S\sigma(\alpha)S^{-1}\sigma_{0}(\alpha^{-1})f(\tau) \\ &= S\rho(x)S^{-1}\sigma_{1}(\alpha)f(\tau). \end{split}$$

This shows that  $\sigma_1(\alpha)$  commutes with  $S\rho(x)S^{-1}=M_x$  and consequently  $\sigma_1(\alpha)$  commutes with the von Neumann algebra generated by  $M_x$ . It is known [[5] cor. 1.1] that a commutative von Neumann algebra with a cyclic vector is maximal Abelian. Therefore  $\sigma_1(\alpha)$  belongs to the von Neumann algebra generated by  $(M_x:x\in G_1)$  which is the algebra of multiplication by essentially bounded measurable functions on  $(\hat{G}_1,\mu)$ . Hence  $\sigma_1(\alpha)f(\tau)=a(\tau,\alpha)f(\tau)$  where  $a(\tau,\alpha)$  is, for each  $\alpha$  a measurable essentially bounded function of modulus 1. We introduce the operator  $M_a$  in  $L^2(\hat{G}_1,\mu)$  where  $(M_af)(\tau)=a(\tau)f(\tau)$ .

From the equation  $S\sigma(\alpha)S^{-1}\sigma_0(\alpha^{-1})=M_\alpha$  we obtain  $S\sigma(\alpha)S^{-1}=M_\alpha\sigma_0(\alpha)$ : that is

$$S\sigma(\alpha)S^{-1}f(\tau) = a(\tau,\alpha)\sqrt{\frac{d\mu_{\alpha}}{d\mu}}(\tau)f([\tau]\alpha).$$

Finally,

$$S\sigma(\alpha_{1} \alpha_{2})S^{-1}f(\tau) = a(\tau, \alpha_{1} \alpha_{2}) \sqrt{\frac{d\mu_{\alpha_{1}\alpha_{2}}}{d\mu}}(\tau)f([\tau]\alpha_{1} \alpha_{2})$$

$$S\sigma(\alpha_{1})\sigma(\alpha_{2})S^{-1}f(\tau) = S\sigma(\alpha_{1})S^{-1}S\sigma(\alpha_{2})S^{-1}f(\tau)$$

$$= S\sigma(\alpha_{1})S^{-1}a(\tau, \alpha_{2}) \sqrt{\frac{d\mu_{\alpha_{2}}}{d\mu}}(\tau)f([\tau]\alpha_{2})$$

$$= a(\tau, \alpha_{1}) \sqrt{\frac{d\mu_{\alpha_{1}}}{d\mu}}(\tau)\alpha([\tau]\alpha_{1}, \alpha_{2}).$$

$$\sqrt{\frac{d\mu_{\alpha_{2}}}{d\mu}}([\tau]\alpha_{1})f([\tau]\alpha_{1}\alpha_{2})$$

$$= a(\tau, \alpha_{1})a([\tau]\alpha_{1}, \alpha_{2}) \sqrt{\frac{d\mu_{\alpha_{1}\alpha_{2}}}{d\mu}}(\tau)$$

$$\sqrt{\frac{d\mu_{\alpha_{1}}}{d\mu}}(\tau)f([\tau]\alpha_{1}\alpha_{2})$$

$$= a(\tau, \alpha_{1})a([\tau]\alpha_{1}, \alpha_{2}) \sqrt{\frac{d\mu_{\alpha_{1}\alpha_{2}}}{d\mu}}(\tau)f([\tau]\alpha_{1}\alpha_{2}).$$

Since 
$$S\sigma(\alpha_1 \alpha_2)S^{-1} = S\sigma(\alpha_1)\sigma(\alpha_2)S^{-1}$$
 we have 
$$\alpha(\tau, \alpha_1 \alpha_2) = \alpha([\tau]\alpha_1, \alpha_2)\alpha(\tau, \alpha_1), \text{ a.e.}$$

This completes the proof of the theorem.

DEFINITION 2.2. A Borel measure  $\mu$  on  $\hat{G}_1$  is said to be  $G_2$ -ergodic if 1.  $\mu$  is  $G_2$ -quasi invariant, and

2. the  $G_2$ -quasi-invariant non zero measures on  $\hat{G}_2$  which are absolutely continuous with respect to  $\mu$  are equivalent to  $\mu$ .

THEOREM 2. Let  $G_1$  and  $G_2$  be as in the paragraph preceding Definition 2.1. Let  $\Pi: (x, \alpha) \to \Pi(x, \alpha) = \rho(x)\sigma(\alpha)$  be a representation of  $G_1 \otimes G_2$ . If the measure  $\mu$  defined by the cyclic representation  $\rho$  is  $G_2$  ergodic, then  $\Pi$  is irreducible.

PROOF. Suppose a closed linear manifold  $\mathfrak{M}$  of  $\mathfrak{H}(\Pi)$  is invariant for  $\Pi$ . Then clearly  $\mathfrak{M}$  is invariant for  $\rho$  and  $\sigma$ . Let E be the projection whose range is  $\mathfrak{M}$ . E belongs to  $R(\rho, \rho)$ . The representation  $\rho$  being cyclic, the von Neumann algebra  $R(\rho, \rho)'$ , generated by the operators  $\rho(x): x \in G_1$ , is a commutative von Neumann algebra with a cyclic element. Consequently [[5]. cor. 1.1].  $R(\rho, \rho)'$  is maximal Abelian. Therefore  $R(\rho, \rho') = R(\rho, \rho)$ . Since every projection of  $R(\rho, \rho)'$  is of the form  $P_B$ , where  $P: B \to P_B$  is the projection valued measure defined by  $\rho$ , there is a Borel set  $B_0$  of  $\hat{G}_1$  such that  $E = P_{B_0}$ .

Let  $\mu_0(B) = \mu(B_0 \cap B)$ . Clearly  $\mu_0$  is absolutely continuous with respect to  $\mu$ . We shall show that  $\mu_0$  is  $G_2$ -quasi invariant. The measure  $\mu$  is equivalent to the measure  $\nu$  where  $\nu(B) = ||P_B \xi_0||^2$ . We may for the purpose of this proof assume, without loss of generality, that  $\mu(B) = ||P_B \xi_0||^2$ . From equation (5) in the proof of Theorem 2.1 we have

$$\sigma(\alpha)P_{B_0\cap B}\sigma(\alpha^{-1})=P_{[B_0\cap B]\alpha^{-1}}.$$

However,

$$\sigma(\alpha)P_{B_0 \cap B} \sigma(\alpha^{-1}) = \sigma(\alpha)P_{B_0} P_B \sigma(\alpha^{-1})$$
$$= \sigma(\alpha)P_{B_0} \sigma(\alpha)^{-1} \sigma(\alpha)P_B \sigma(\alpha^{-1}).$$

Now suppose  $\mu_0(B)=0$ . Then  $\mu(B_0\cap B)=0$ , and by the  $G_2$ -quasi invariance of  $\mu$ , it follows that  $\mu([B_0\cap B]\alpha^{-1})=0$ . Consequently,

$$0 = ||P_{[B_0 \cap B]\alpha^{-1}} \xi_0||^2$$

$$= ||P_{B_0 \cap [B]\alpha^{-1}} \xi_0||^2$$

$$= \mu(B_0 \cap [B]\alpha^{-1}) = \mu_0([B]\alpha^{-1}).$$

Since  $\alpha$  in  $G_2$  is arbitrary, we have shown that  $\mu_0$  is  $G_2$ -quasi invariant. The measure  $\mu$  is  $G_2$ -ergodic. Therefore either  $\mu_0$  is equivalent to  $\mu$  or  $\mu_0$  is the zero measure. That is either  $B_0 = \hat{G}_1$  or  $B_0 = \phi$ . Consequently,  $\mathfrak{M} = \mathfrak{H}$  or  $\mathfrak{M} = \{0\}$ .

This completes the proof.

DEFINITION 2.3. Let  $\Pi_i: (x, \alpha) \to \Pi_i(x, \alpha) = \rho_i(x)\sigma_i(\alpha)$  be representations of  $G_1$  s  $G_2$  in  $\mathfrak{H}(\Pi_i)$ , i = 1, 2.  $\Pi_i$  is said to be equivalent to  $\Pi_2$  if there is a linear isometry  $S: \mathfrak{H}(\Pi_1) \to \mathfrak{H}(\Pi_2)$  such that

$$S\rho_1(x)S^{-1} = \rho_2(x) \quad S\sigma_1(\alpha)S^{-1} = \sigma_2(\alpha).$$

Theorem 2.3. Let  $\Pi_i:(x,\alpha)\to\Pi_i(x,\alpha)$  be representations of  $G_1 \otimes G_2$  on  $\mathfrak{H}$   $(\Pi_i)$  where

$$\Pi_i(\circ, \varepsilon): x \to \Pi_i(x, \varepsilon) \quad i = 1, 2$$

are cyclic. A set of necessary and sufficient condition that  $\Pi_1$  is equivalent to to  $\Pi_2$  is

- 1.  $\mu^1$  is equivalent to  $\mu^2$  where  $\mu^i$  is the measure on  $\hat{G}_i$  defined by  $\Pi_i$   $(0, \varepsilon)$  i = 1, 2; and
- 2. there exists a Borel function b on  $\hat{G}_1$  with the properties
  - 2.1.  $|b(\tau)| = 1$  almost everywhere, and
  - 2.2.  $a_2(\tau, \alpha) = b(\tau)a_1(\tau, \alpha)b^{-1}([\tau]\alpha)$  where  $a_i(\tau, \alpha)$  is the function associated with  $\Pi_i(e, \circ) : \alpha \to \Pi_i(e, \alpha)$  in theorem 2.1.

PROOF. It is evident from Theorem 2.1 that,  $\Pi_1$  is equivalent to  $\Pi_2$  if and only if the following is true: (\*) there is a linear isometry  $S: L^2$   $(\hat{G}_1, \mu^1) \to L^2(\hat{G}_1, \mu^2)$  such that  $S\rho_1(x) = \rho_2(x)S$  where

$$\rho_i(x)f(\tau) = x(\tau)f(\tau), f \in L^2(\widehat{G}_1, \mu^i)$$

and  $S\sigma_1(\alpha) = \sigma_2(\alpha)S$ , where

$$\sigma_i(\alpha)(\tau) = a_i(\tau, \alpha) \sqrt{\frac{d\mu_{\alpha}^i}{du^i}}(\tau) f([\tau]\alpha), \ i = 1, 2.$$

Assume that the conditions (\*) are satisfied. We recall that  $L(\hat{G}_1)$ , the set of all continuous functions with compact support, is dense in  $L^p(G_1, \mu^i)$  where p=1,2 and i=1,2. In the course of the proof of lemma 1.2 we saw that the operators  $\rho_i(g)$  where  $(\rho_i(g)f)(\tau)=g(\tau)f(\tau), g\in L(\hat{G}_1)$  and  $f\in L^2(\hat{G}_1,\mu^i)$  belong to  $R(\rho_i,\rho_i)'$ . It is easily verified that  $S\rho_1(x)S^{-1}$   $\rho_2(x)$  implies  $S\rho_1(g)S^{-1}=\rho_2(g)$  for all  $g\in L(\hat{G}_1)$ .

Since  $S\rho_1(x)S^{-1}=\rho_2(x)$  for all x in  $G_1$ , the commutative von Neumann algebra  $R(\rho_1,\rho_1)'$  generated by  $(\rho_1(x):x\in G)$  is unitarily equivalent to the von Neumann algebra  $R(\rho_2,\rho_2)'$  generated by  $(\rho_2(x):x\in G_1)$ . Since  $\rho_i$  are cyclic representations, the commutative von Neumann algebras  $R(\rho_i,\rho_i)'$  are cyclic. A commutative von Neumann algebra with a cyclic vector is maximal Abelian ([5] corollary 1.1) and is unitarily equivalent to a multiplication algebra ([5] Lemma 1.2). Consequently, the multiplication algebra on  $L^2(\hat{G}_1,\mu^1)$  is unitarily equivalent to the multiplication algebra on  $L^2(\hat{G}_1,\mu^2)$  and therefore ([6] Theorem 4.1)  $\mu^1$  is equivalent to  $\mu^2$ .

The function e, where  $e(\tau) = 1$  for all  $\tau \in \hat{G}_1$ , belongs to  $L^2(\hat{G}_1, \mu^1)$ . Let  $Se = c \in L^2(\hat{G}_1, \mu^2)$ . We shall show that c is an essentially bounded function. If  $g \in L(\hat{G}_1)$ , we have

$$Sg = Sge = S\rho_1(g)e = S\rho_1(g)S^{-1}Se$$
  
=  $\rho_2(g)Se = \rho_2(g)c$ . (i)

Let

$$C(g) = \int_{\hat{G}_{1}} |c(\tau)|^{2} g(\tau) d\mu^{2}(\tau)$$

$$|C(g)| = (gc, c) = (\rho_{2}(g)c_{i} c) = (\rho_{2}(g)Se, Se)$$

$$= (S^{-1}\rho_{2}(g)Se, e) = (\rho_{2}(g)e, e)$$

$$= \int_{\hat{G}_{1}} g(\tau) d\mu^{1}(\tau).$$
(ii)

Hence

$$|C(g)| \le ||g||_1$$
 (the  $L^1$ -norm of  $g \in L^1(\hat{G}_1, \mu^1)$ .

That is, C(g) is bounded on a dense linear subset  $L(\hat{G}_1)$  of  $L^1(\hat{G}_1, \mu^1)$ , and can therefore be extended to  $L^1(\hat{G}_1, \mu^1)$ . Hence  $C \in L^{\infty}(\hat{G}_1, \mu^1)$ , and therefore c is essentially bounded with respect to  $\mu^1$ . Since  $\mu^1$  and  $\mu^2$  are equivalent it follows that c is essentially bounded with respect to  $\mu^2$ .

Since the function c is essentially bounded the equation (i) can be written in the form  $Sg = M_c g$  where  $M_c$  is the operation of multiplying by c. Since  $M_c$  is a bounded operator and  $L(\hat{G}_1)$  is dense in  $L^2(\hat{G}_1, \mu)$ , the equation  $Sg = M_c g$  holds for all g in  $L^2(\hat{G}_1, \mu^1)$ . It follows from the equivalence of  $\mu^1$  and  $\mu^2$  and the equation (ii) that

$$\begin{split} \int_{\hat{G}_1} g(\tau) |c(\tau)|^2 d\mu^2(\tau) &= \int_{\hat{G}_1} g(\tau) d\mu^1(\tau) \\ &= \int_{\hat{G}_1} g(\tau) \frac{d\mu^1}{d\mu^2}(\tau) d\mu^2(\tau). \end{split}$$

Hence

$$|c(\tau)|^2 = \frac{d\mu^1}{d\mu^2}(\tau)$$

almost everywhere, and

$$c(\tau) = b(\tau) \sqrt{\frac{d\mu^{1}}{d\mu^{2}}}(\tau)$$
$$|b(\tau)| = 1$$

where

almost everywhere.

Now,

$$\begin{split} S\sigma_{1}(\alpha)(\tau) &= M_{c} a_{1}(\tau, \alpha) \sqrt{\frac{d(\mu^{1})_{\alpha}}{d\mu^{1}}}(\tau)g([\tau]\alpha) \\ &= b(\tau) \sqrt{\frac{d\mu^{1}}{d\mu^{2}}}(\tau)a_{1}(\tau, \alpha) \sqrt{\frac{d(\mu^{1})_{\alpha}}{d\mu^{1}}}(\tau)g([\tau]\alpha) \\ &= b(\tau)\alpha_{1}(\tau, \alpha) \sqrt{\frac{(d\mu^{1})_{\alpha}}{d\mu^{2}}}(\tau)g([\tau]\alpha). \end{split}$$

i.e.

$$\begin{split} \sigma_2(\alpha)Sg &= \sigma_2(\alpha)b(\tau)\sqrt{\frac{d\mu^1}{d\mu^2}}(\tau)g(\tau) \\ &= a_2(\tau,\alpha)\sqrt{\frac{d(\mu^2)_\alpha}{d\mu^2}}(\tau)b([\tau]\alpha)\sqrt{\frac{d\mu^1}{d\mu^2}}([\tau]\alpha)g([\tau]\alpha) \\ &= a_2(\tau,\alpha)b(\tau\alpha)\sqrt{\frac{d(\mu^2)_\alpha}{d\mu^2}}(\tau)\sqrt{\frac{d(\mu^2)_\alpha}{d(\mu^2)_\alpha}}(\tau)g(\tau\alpha) \\ &= a_2(\tau,\alpha)b([\tau]\alpha)\sqrt{\frac{d(\mu^1)_\alpha}{d\mu^2}}(\tau)g([\tau]\alpha). \end{split}$$

Hence the equation  $S\sigma_1(\alpha)g = \sigma_2(\alpha)Sg$  yields

$$b(\tau)\alpha_1(\tau,\alpha) = \alpha_2(\tau,\alpha)b([\tau]\alpha), \text{ a.e.}$$
$$\alpha_2(\tau,\alpha) = b(\tau)\alpha_1(\tau,\alpha)b^{-1}([\tau]\alpha) \text{ a.e.}$$

The converse is easy to verify and we omit the details. This completes the proof.

The condition 2 of the last theorem can be reformulated in terms of a one dimensional cohomology group. To this end we observe first that  $G_2$  as a group of automorphisms of  $L^{\infty}(\hat{G}_1, \mu) : \alpha[g](\tau) = g([\tau]\alpha)$ . Furthermore, the function  $\alpha(\tau, \alpha)$  of Theorem 2.1 defines a mapping  $\tilde{\alpha}: G_2 \to L^{\infty}(\hat{G}_1, \mu)$  where  $(\tilde{\alpha}(\alpha))(\cdot) = \alpha(\cdot, \alpha)$ . From ii of theorem 2.1 we see that  $\tilde{\alpha}$  is a crossed homomorphism. It is evident that  $(\tilde{b}(\alpha))(\cdot) = b(\cdot)$   $b^{-1}([\cdot]\alpha)$ , where  $b \in L^{\infty}$ , is a principal crossed homomorphism. In view of these observations the condition 2 of Theorem 2.3 states  $\alpha_1$  and  $\alpha_2$  define the same element of the one dimensional cohomology group  $H^1(G_2, L^{\infty})$ .
