# ON THE STRUCTURE OF CERTAIN SEMI-GROUPS OF SPHERICAL KNOT CLASSES 

By Barry MAZUR

## § 1. Introduction.

The problem of classification of $k$-sphere knots in $r$-spheres is the problem of classifying "knot pairs": $\mathrm{S}=\left(\mathrm{S}_{1}, \mathrm{~S}_{2}\right)$, where $\mathrm{S}_{2}$ is an oriented combinatorial $r$-sphere, $\mathrm{S}_{1}$ a subcomplex of $\mathrm{S}_{2}$ (isomorphic to a standard $k$-sphere), and the pair S is considered equivalent to $\mathrm{S}^{\prime}\left(\mathrm{S} \sim \mathrm{S}^{\prime}\right)$ if there is a combinatorial orientation-preserving homeomorphism of $S_{1}$ onto $S_{1}^{\prime}$ bringing $S_{2}$ onto $S_{2}^{\prime}$.

Thus it is the problem of classifying certain relative combinatorial structures. The set of all such, for fixed $k$ and $r$, will be called $\Sigma_{k}^{r}$, and can be given, in a natural manner, the structure of a semi-group. There is a certain sub-semi-group of $\Sigma_{k}^{r}$ to be singled out - the semi-group $\mathrm{S}_{k}^{r}$ of all pairs $\mathrm{S}=\left(\mathrm{S}_{1}, \mathrm{~S}_{2}\right)$ where $\mathrm{S}_{1}$ is smoothly imbedded in $S_{2}$ (locally unknotted).

In this paper I shall define a notion of equivalence (which I call *-equivalence) between knot pairs which is (seemingly) weaker than the equivalence defined above.

Two knot pairs $S$ and $\mathrm{S}^{\prime}$ are $*$-equivalent if (again) there is an orientation-preserving homeomorphism

$$
\varphi: S_{2} \rightarrow S_{2}^{\prime}
$$

bringing $S_{1}$ onto $S_{1}^{\prime}$. However $\varphi$ is required to be combinatorial (not on all of $S_{2}$, as before, but) merely on $\mathrm{S}_{2}^{*}=\mathrm{S}_{2}-\left(p_{1}, \ldots, p_{n}\right)$, where $p_{1}, \ldots, p_{n} \in \mathrm{~S}_{2}$, where $\mathrm{S}_{2}^{*}$ is considered as an open infinite complex. Thus *-equivalence neglects some of the combinatorial structure of the pair $\left(\mathrm{S}_{1}, \mathrm{~S}_{2}\right)$. The set of all $*$-equivalence classes of knot pairs forms a semi-group again, called ${ }^{*} \Sigma_{k}^{r}$.

Finally the subsemi-group of smoothly imbedded knots in ${ }^{*} \Sigma_{k}^{r}$ I call * ${ }_{k}^{r}$. The purpose of this paper is to prove a generalized knot theoretic restatement of lemma 3 in [ $\mathbf{r}]$.

Inverse Theorem: A knot $\mathrm{S}_{k}^{r}$ is invertible if and only if it is $*$-trivial.
And in application, derive the following fact concerning the structure of the knot semi-groups:

There are no inverses in ${ }^{*} \mathrm{~S}_{k}^{\tau}$.

## § 2. Terminology.

My general use of combinatorial topology terms is as in [2]. It is clear what is meant by the "usual" or "standard" imbedding of a $k$-sphere or a $k$-cell in $\mathrm{E}^{r}$. Similarly an unknotted sphere or disc in $\mathrm{E}^{r}$ means one that may be thrown onto the usual by a combinatorial automorphism of $\mathrm{E}^{r}$.

Definition i. Let $\mathbf{M}^{k}$ be a subcomplex (a $k$-manifold) of $\mathrm{E}^{r}$. Then $\mathbf{M}^{k}$ is locally unknotted at a point $m(m \in \mathbf{M})$ if the following condition is met with:
i) There is an $r$-simplex $\Delta^{r}$ drawn about $m$ so that $\Delta^{r} \cap \mathrm{McSt}(m)$, and $\Delta^{r} \cap \mathrm{M}$ is then a $k$-cell $\mathrm{B}^{k} c \Delta^{r}$, and $\partial \mathrm{B}^{k} \mathrm{c} \partial \Delta^{r}$.
2) There is a combinatorial automorphism of $\Delta^{r}$, sending $\mathrm{B}^{k}$ onto the "standard $k$-cell in $\Delta^{r \prime}$. M is plain locally unknotted if it is locally unknotted at all points.

Semi-Groups:
All semi-groups to be discussed will be countable, commutative, and possess zero elements.

Definition 2. A semi-group F is positive if:

$$
\mathrm{X}+\mathrm{Y}=\mathrm{o} \text { implies } \mathrm{X}=\mathrm{o}
$$

(i.e.if F has no inverses).

Definition 3. A minimal base of a semi-group F is a collection $\mathrm{J}=\left(\chi_{1}, \ldots\right)$ of elements of $F$ such that every element of $F$ is a sum of elements in $J$, and there is no smaller $\mathrm{J}^{\prime} \subset \mathrm{J}$ with the same property.

Definition 4. A prime element $p$ in the semi-group F is an element for which $p=x+y$ implies either $x=0$ or $y=0$.

Clearly, if a positive semi-group F possesses a minimal base, that minimal base has to be precisely the set of primes in F, and F has the property that every element is expressible as a finite sum of primes.

Definition 5. An element $x \in \mathrm{~F}$ is invertible if there is a $y \in \mathrm{~F}$ such that

$$
x+y=0 .
$$

## § 3. (*)-homeomorphism.

Definition 6. A $\left(p_{1}, \ldots, p_{n}\right)$-homeomorphism, $h: \mathrm{E}^{r} \rightarrow \mathrm{E}^{r}$ will be an orientation preserving homeomorphism which is combinatorial except at the points $p_{i} \in \mathrm{E}^{r}$. It is a homeomorphism such that $h \mid \mathrm{E}^{r}-\left(p_{i}\right)$ is a combinatorial map - simplicial with respect to a possibly infinite subdivision of the open complexes involved. When there is no reason to call special attention to the points $p_{1}, \ldots, p_{n}$, I shall call such: a (*)homeomorphism.

Definition 7. Two subcomplexes $\mathrm{K}, \mathrm{K}^{\prime} \subset \mathrm{E}^{r}$ will be called *-equivalent ( $\mathrm{K} \sim \mathrm{K}^{\prime}$ ) if there is a $*$-homeomorphism $h$ of $\mathrm{E}^{r}$ onto itself bringing K onto $\mathrm{K}^{\prime}$. (If $h$ is a ( $p_{i}$ )homeomorphism I shall also say $\mathrm{K}_{\left(\tilde{p}_{i}\right)} \mathrm{K}^{\prime}$.) To keep from using too many subscripts, whenever a (*)-equivalence comes up in a subsequent proof, I shall act as if it were a ( $p$ )-equivalence for a single point $p$. This logical gap, used merely as a notationsaving device, can be trivally filled by the reader.

I'll say a sphere knot is $*$-trivial if it is $*$-equivalent to the standard sphere.

## § 4. Knot Addition.

There is a standard additive structure that can be put on $\Sigma_{k}^{r}$, the set of combinatorial $k$-sphere knots in $\mathrm{E}^{r}$ (two $k$-sphere knots are equivalent if there is an orientationpreserving combinatorial automorphism of $\mathrm{E}^{r}$ bringing the one knot onto the other). (For details see [2]).

I shall outline the procedure of "adding two knots" $\mathrm{S}_{0}$, $\mathrm{S}_{1}$. Separate $\mathrm{S}_{0}$ and $\mathrm{S}_{1}$ by a hyperplane H (possibly after translating one of them). Take a $k$-simplex $\Delta_{i}$ from each $\mathrm{S}_{i}, i=\mathrm{o}$, I. And lead a "tube" from $\Delta_{0}$ to $\Delta_{1}$ (by "thickening" a polygonal arc joining a point $p_{0} \in \Delta_{0}$ to $p_{1} \in \Delta_{1}$, which doesn't intersect the $S_{i}$ except at $\Delta_{i}$ ). Then remove the $\Delta_{i}$ and replace them by the tube $\mathrm{T}=\mathrm{S}^{k-1} \times \mathrm{I}$, where one end, $\mathrm{S}^{k-1} \times \mathrm{o}$ is attached to $\partial \Delta_{0}$ by a combinatorial homeomorphism, and the other $\mathrm{S}^{k-1} \times \mathrm{I}$ is attached to $\partial \Delta_{1}$ similarly. The resulting knot is called the sum: $S_{0}+S_{1}$, and its knot-equivalence class is unique.

If one added the point at infinity to $\mathrm{E}^{r}$, to obtain $\mathrm{S}^{r}$, the hyperplane H would become an unknotted $\mathrm{S}^{r-1} \mathrm{C} \mathrm{S}^{r}$, separating the knot $\mathrm{S}_{0}+\mathrm{S}_{1}$ into its components $\mathrm{S}_{0}$ and $\mathrm{S}_{1}$. In analytic fashion, then, we can say that a $k$-sphere knot $S \subset S^{r}$ is split by an $S^{r-1} c S^{r}$ if:

1) $\mathrm{S}^{r-1} \mathrm{n}$ S is an unknotted ( $k-\mathrm{I}$ )-sphere knot in S .
2) $\mathrm{S}^{r-1}$ is unknotted in $\mathrm{S}^{r}$.
3) $\mathrm{S}^{r-1} \mathrm{n} \mathrm{S}$ is unknotted in $\mathrm{S}^{r-1}$.

Let $A_{0}$ and $A_{1}$ be the two complementary components of $S^{r-1} \cap S$ in $S$, and let $B$ be an unknotted $k$-disc that $S^{r-1} \cap S$ bounds in $S^{r-1}$. Then $S_{0}=A_{0} \cup B, S_{1}=A_{1} \cup B$ are knotted spheres again, and clearly $S \sim S_{0}+S_{1}$.

Thus I'll say: $\mathrm{S}^{r-1}$ splits S into $\mathrm{S}_{0}+\mathrm{S}_{1}$; if $\mathrm{E}_{0}$ and $\mathrm{E}_{1}$ are the complementary regions of $\mathrm{S}^{r-1}$ in $\mathrm{S}^{r}$, I'll refer to $\mathrm{S}_{1}$ as that « part of $S$ » lying in $E_{1}$, and similarly for $\mathrm{S}_{0}$. Working in the semi-group ${ }^{*} \Sigma_{k}^{r}$, one can be slightly cruder, and say: $S^{r-1} *$-splits $S$ if only 1 ) and 3) hold. Clearly by [ $\mathbf{r}$ ], every $\mathrm{S}^{r-1}$ is $*$-trivial in $\mathrm{S}^{r}$.

Lemma i: If $\mathrm{S}^{r-1} *$-splits S , and $\mathrm{S}_{0}, \mathrm{~S}_{1}$ are constructed in a manner analogous to the above, then $S_{*} S_{0}+S_{1}$.

## § 5. The Semi-Groups of Spherical Knots.

This operation of addition, discussed in the previous section, turns $\Sigma_{k}^{r}$ into a commutative semi-group with zero. Our object is to study the algebraic structure of the
subsemi-group $\mathrm{S}_{k}^{r} c \Sigma_{k}^{r}$ of locally unknotted $k$-sphere knots. Let ${ }^{*} \Sigma_{k}^{r}$ be the semi-group of classes of spherical knots under *-equivalence. Let $\mathrm{G}_{k}^{r} \subset \Sigma_{k}^{r}$ be the maximal subgroup of $\Sigma_{k}^{r}$, that is: the subgroup of invertible knots.

Inverse Theorem: There is an exact sequence

$$
o \rightarrow \mathrm{G}_{k}^{r} \rightarrow \mathrm{~S}_{k}^{r} \rightarrow{ }^{*} \mathrm{~S}_{k}^{r} \rightarrow 0
$$

(where ${ }^{*} \mathrm{~S}_{k}^{r}$ is the image of $\mathrm{S}_{k}^{r}$ in ${ }^{*} \Sigma_{k}^{r}$ )
or, equivalently, a knot in $\mathrm{S}_{k}^{r}$ is $*$-trivial if and only if it is invertible.

## § 6. Proof of the Inverse Theorem.

a) If S is invertible, then $\mathrm{S}_{(*)} \mathrm{o}$. The proof is quite as in [ $\left.\mathbf{I}\right]$. Let $\mathrm{S}+\mathrm{S}^{\prime} \sim \mathrm{o}$. Then consider the knots:

$$
\begin{aligned}
& \mathrm{S}_{\infty}=\mathrm{S}+\mathrm{S}^{\prime}+\mathrm{S}+\mathrm{S}^{\prime}+\ldots \mathrm{U} p_{\infty} \\
& \mathrm{S}_{\infty}^{\prime}=\mathrm{S}^{\prime}+\mathrm{S}+\mathrm{S}^{\prime}+\mathrm{S}+\ldots \mathrm{p} p_{\infty}
\end{aligned}
$$

and notice: (as was done in detail in [ $\mathbf{r}]$ )

Fig. 1
Lemma 2: There is a (*)-homeomorphism

$$
\begin{aligned}
& f: \mathrm{E}^{r} \rightarrow \mathrm{E}^{r} \text { such that } \\
& f: \mathrm{S} \rightarrow \mathrm{~S}+\mathrm{S}_{\infty}^{\prime} .
\end{aligned}
$$

Proof: Let D be the $k$-cell on which the addition of S to $\mathrm{S}_{\infty}^{\prime}$ takes place. Since $\mathrm{S}_{\infty}^{\prime} \underset{\left(p_{\infty}\right)}{ } \mathrm{o}$, we may transform figure I to figure 2 by a $\left(p_{\infty}\right)$-homeomorphism $g$ which leaves everything to the left of the hyperplane $\mathrm{H}_{1}$ fixed, and sends $\mathrm{S}^{\prime}$ to the " standard $k$-sphere" to the right of $\mathrm{H}_{1}$. (See figure 2.)

Fig. 2
Then, in figure 2, clearly one can construct an automorphism $f^{\prime}$ which leaves S fixed and sends D onto $g\left(\mathrm{~S}_{\infty}^{\prime}\right)$-int D.

Take $f=g^{-1} f^{\prime} g$, and $f$ has the properties required, and is a (*)-homeomorphism. Therefore, by the above lemma,

$$
S_{(* *} S+S_{\infty}^{\prime}=S_{\infty} \underset{(*)}{ } 0
$$

and finally:

$$
S_{(*)} 0
$$

which proves (a).
b) If $\mathrm{S} \in \mathrm{S}_{k}^{r}$ and $\mathrm{S}_{(\overline{p)}}$, then S is invertible.

Proof: First observe that if $k=r-1$, invertibility of knots is generally true (by [ $\mathbf{1}]$ ), and so we needn't prove anything.

Lemma 3: If $k<r-\mathrm{I}$, and $\mathrm{S} \in \mathrm{S}_{k}^{r}, \mathrm{~S}_{\widetilde{(p)}}$ ofor $p \notin \mathrm{~S}$, then $\mathrm{S} \sim \mathrm{o}$.
Proof: There is an $r$-cell $\Delta$ containing S but not $p$. Then $f \mid \Delta$ is combinatorial, and by a standard lemma:

Lemma 4: If $g: \Delta \rightarrow \Delta^{\prime}$ is a combinatorial homeomorphism of an $r$-cell $\Delta \mathrm{CE}^{r}$ to an $r$-cell $\Delta^{\prime} \subset \mathrm{E}^{r}$, then $g$ can be extended to a combinatorial automorphism of $\mathrm{E}^{r}$ (see [2]). Thus, restrict $f$ to $\Delta$, and extend $f \mid \Delta$ to a combinatorial automorphism $g$ of $\mathrm{E}^{r}$. This $g$ yields the equivalence $S \sim 0$. Therefore, assume $S_{(p)} 0$, and $p \in S$.

Fig. 3
Let B be a small $r$-cell about $p$, so that $\mathrm{C}=\mathrm{B} \cap \mathrm{S}$ is in $\mathrm{St}(p)$, and hence an unknotted $k$-cell, by the local unknottedness of $\mathrm{S} . \quad \partial \mathrm{B} \cap \mathrm{S}=\partial \mathrm{C}$ and $\partial \mathrm{C}$ is unknotted in $\partial \mathrm{B}$.

Let $f$ be the ( $p$ )-homeomorphism taking S onto the standard $\mathrm{S}^{k}$.

Fig. 4

Now let D be an unknotted disc, the image of a perturbation of $f(\mathbf{C})$ with the properties:
i) $\partial(f(\mathbf{C}))=\partial \mathbf{D}$;
ii) int Dcint B ;
iii) $f(p) \notin \mathrm{D}$;
iv) the knot $\mathrm{K}=\mathrm{D} \mathbf{u}\left(\mathrm{S}^{k}-f(\mathrm{C})\right)$ is still trivial.

Then $f^{-1}$ takes K to a knot $\mathrm{K}^{\prime}=f^{-1}(\mathrm{~K})$, split by $\partial \mathrm{B}$ into the sum:

$$
\mathrm{K}^{\prime}=\mathrm{S}+\mathrm{S}^{\prime}
$$

where $S$ is the knot lying in the exterior component of $\partial \mathrm{B}$, and $\mathrm{S}^{\prime}$ in the interior.

But $\mathrm{K} \sim 0$, and $\mathrm{K}_{f(p)}^{\prime} \mathrm{K}$ where $f(p) \notin f(\mathrm{~K})$, therefore by lemma 3, $f(\mathrm{~K}) \sim \mathrm{K}$. So:

$$
\mathrm{S}+\mathrm{S}^{\prime} \sim f(\mathrm{~K}) \sim \mathrm{K} \sim \mathrm{o}
$$

and $\mathrm{S}^{\prime}$ is invertible.
Corollary: ${ }^{*} \mathrm{~S}_{k}^{r}$ is a positive semi-group.
So we have that ${ }^{*} S_{k}^{r}$ is precisely $\mathrm{S}_{k}^{r}$ « modulo units».

## § 7. Infinite Sums in ${ }^{*} \boldsymbol{\Sigma}_{k}{ }^{\boldsymbol{r}}$.

Let $\mathrm{X}_{i}, i=\mathrm{I}, \ldots$, be knots representing the classes $\chi_{i} \in \Sigma_{k^{r}}^{r}$. Define $\sum_{i=1}^{\infty} \mathrm{X}_{i}$ to be the infinite one point compactified sum of the knots $X_{i}$, in that order (figure 5).

Fig. 5
As it stands, $\mathrm{X}=\sum_{i=1}^{\infty} \mathrm{X}_{i}$ will not represent a knot in $\Sigma_{k}^{r}$, because X is not combinatorially imbedded (at $p_{\infty}$ ).

Definition 8. $\sum_{i=1}^{\infty} \mathrm{X}_{i}=\mathrm{X}$ converges if there is a $\left(p_{\infty}\right)$-homeomorphism $\mathrm{H}: \mathrm{X} \rightarrow \mathrm{Y}$, where Y is combinatorially imbedded. In that case, the knot class $y \epsilon^{*} \Sigma_{k}^{r}$ is uniquely determined by the $\mathrm{X}_{i} \in \Sigma_{k}^{r}$, and I shall say $\sum_{i=1}^{\infty} \chi_{i}=y$.

If $\sum_{i=1}^{\infty} \chi_{i}$ is in ${ }^{*} \mathrm{~S}_{k}^{r}$, I'll say that $\sum_{i=1}^{\infty} \chi_{i}{ }_{i}$ converges in ${ }^{*} \mathrm{~S}_{k}^{r}$.
Theorem r. If $\sum_{i=1}^{\infty} \chi_{i}$ converges in ${ }^{*} \mathrm{~S}_{k}^{r}$, then it does so finitely. That is, there is an N such that

$$
\chi_{i} \tau_{x}, \quad i>N .
$$

Proof: Notice that by the inverse theorem, there are no inverses in ${ }^{*} \mathrm{~S}_{k}^{r}$.
Let $\mathrm{X}=\sum_{i=1}^{\infty} \mathrm{X}_{i}$, and $\mathrm{H}: \mathrm{X} \rightarrow \mathrm{Y}$ where Y is a subcomplex of $\mathrm{E}^{r}$ and H a (*)-homeomorphism.

Fig. 6
Let B be a ball about $p^{\prime}$ such that $\mathrm{B} \cap \mathrm{Y}$ is a disc in $\operatorname{St}\left(p^{\prime}\right)$, and by the local unknottedness of $\mathrm{Y}, \dot{\partial} \mathrm{B}$ splits Y into two knots,

$$
\mathrm{Y}=\mathrm{Y}^{(1)}+\mathrm{Y}^{(2)}
$$

where $\mathrm{Y}_{1} \subset B$ is trivial, and $\mathrm{Y} \sim \mathrm{Y}_{2}$.

Fig. 7
Now transform the situation by $H^{-1}$. Let $B^{\prime}=H^{-1}(B)$, and we have that $\partial B^{\prime}$ *-splits X into:

$$
X_{*} X^{(1)}+X^{(2)}
$$

and H yields the $*$-equivalences:

$$
\begin{aligned}
& \mathrm{X}^{(1)} \sim \mathrm{Y}^{(1)} \sim 0 \\
& \mathrm{X}^{(2)} \sim \mathrm{Y}^{(2)}
\end{aligned}
$$

Find an $i$ so large that $\Delta_{i} \subset$ int $\mathbf{B}^{\prime}$. Then $\partial \Delta_{i}$ splits $\mathbf{X}^{(1)}$ further:

$$
\mathrm{X}^{(1)} \sim \mathrm{X}^{(3)}+\mathrm{X}^{(4)}
$$

where $X^{(3)}$ is the part of $X^{(1)}$ lying in $\Delta_{i}$. But then, by figure $6, X^{(3)}$ is nothing more than:

$$
\mathrm{X}^{(3)} \sim \sum_{j=i}^{\infty} \mathrm{X}_{j}
$$

Passing to equivalence classes in ${ }^{*} \mathrm{~S}_{k}^{r}$, one has:

$$
\begin{gathered}
\chi^{(3)}+\chi^{(4)}=0 \\
\chi^{(3)}=\sum_{j=i}^{\infty} \chi_{j}
\end{gathered}
$$

(where $x$ the $*$-equivalence class of X ). But repeated application of the fact that ${ }^{*} \mathrm{~S}_{k}^{r}$ has no inverses yields $\chi_{j}=0$ for $j \geqslant i$, which proves the theorem.
